Lots of GUTs

D.H. Perkins

Fifth Workshop on Grand Unification. Edited by Kyungsik Kang, Herbert Fried and Paul Frampton. *World Scientific/Wiley*: 1984. Pp. 538. \$59.50, £51.75.

THE gravitational force between two protons is 10^{-38} of the electrical force. Where does such an odd number come from? Understanding the interrelation between the fundamental interactions of nature and their possible unification has always been a primary goal of the physicist. Regular conferences and workshops are devoted to the subject, the one in 1984 at Brown University being the fifth in a present series. This book contains the record of the meeting.

The first, and arguably the greatest intellectual leap was taken by Newton 300 years ago, when he proposed that the same universal gravitational force that made the apple fall also held the planets in orbit about the Sun. The next was the unification of electricity and magnetism by Maxwell in 1869. The third was the proposed unification of the weak and electromagnetic interactions by Salam, Weinberg and Glashow in the late 1960s which predicted the existence of the massive bosons W and Z, discovered at CERN two years ago.

Grand unification theories (GUTs) are a proposed further stage, originally identified with unification of the strong quark-quark force with the electroweak, but more recently taken to include gravity as well — thus encompassing all the known interactions in nature.

Maxwell's theory of electromagnetism was quickly verified by the detection of electromagnetic waves by Hertz, and the electroweak theory by the discovery of neutral weak currents in 1973 and the W and Z ten years later. However, despite early promise — the correct prediction of the value of the electroweak mixing angle — there is as yet hardly any experimental support for GUTs. The theory occurs in several versions, all of them making several predictions, none of them so far borne out by experience.

One of the early predictions was that of proton decay. This was not a new idea. Sakharov, in the context of the big bang model of the Universe, had pointed out in 1966 that the mechanism required to generate the huge preponderance of matter over antimatter in the Universe must also be responsible for proton decay at some level. Since 1973, GUTs had predicted a lifetime of around 10^{30} – 10^{33} yr, that is within experimental reach of huge (1 kiloton) detectors.

Papers in the present volume describe results of four experiments carried out deep underground in three continents. Their main achievement has been to ex-

clude one version of GUT: the lower limit on the lifetime for decay of a proton to a positron plus a neutral pion exceeds 10^{32} yr, more than an order of magnitude longer than the prediction. Needless to say, the other versions of GUTs make less definite predictions and so are harder to exclude. Yet all the experiments found candidates for other decay modes at 5–10 per cent of the total event rate, which is dominated by the atmospheric neutrino background. Finding out whether (or how) protons decay is going to be a long experimental struggle, and the question is hardly likely to be resolved by the tenth or even the fifteenth workshop in the series.

Another prediction of some versions of GUT is that leptons are not conserved and

plus re-heat" version of the big bang is that the density of monopoles can be reduced to an acceptable number (one per galaxy, for example). Again, and just as in the case of neutrino oscillations, early possible signals have not been repeated and the most recent and sensitive experiments, seeking to detect monopoles through their ionization or currents induced in superconducting loops, find no evidence for their existence. Astrophysical limits on monopole flux, although inherently less reliable, set even more stringent flux limits.

Grand unified theories incorporating supersymmetry, in which it is postulated that all bosons are mirrored by fermion partners and vice versa, have become fashionable in recent years. None of this host of supersymmetric partners has so far been detected. In $p\bar{p}$ collider data at CERN over the past year, a few mysterious events (monojets) with large missing energy might be consistent with production of gluinos (the fermion counterparts of the gluons mediating the interquark force) — or equally with something else. Latest rumours are that even this possible signal may be vanishing.

Finally, theorists have proposed supergravity models, some of them based on the ideas of Kaluza and Klein of more than half a century ago. These start off with Einstein's theory in many dimensions, all but four of which are compacted and unobservable but which can be interpreted as the other fields (electromagnetic, strong and so on).

This volume gives a blow-by-blow account of the present status of the experimental and theoretical work in this most fundamental area of science. The hard core of practical evidence gives strong support for the old-hat "standard model" — of quark and lepton constituents, of the gauge models of the strong and electroweak interactions — and that is a solid achievement. The standard model is however somewhat ugly and theoretically unattractive because we cannot understand the huge range of particle masses, from less than 10 eV for neutrinos, through 10^{11} eV for the W and Z bosons, to 10^{28} eV for the Planck mass. So the theorists have gone off into what appears to many experimentalists to be esoteric wildernesses which have a beauty and symmetry of their own, and one of which might even provide the final answer. The main problem is that experiments in particle physics are very expensive and complex, and take five to ten years from first inception to final results. Those running now were inspired by the now out-dated theory of a decade ago. In short, we have lots of ideas and questions but, so far, hardly a real clue. □

1873 — Maxwell publishes his work on the unification of electricity and magnetism.

that the different flavours of neutrino may transform one into the other. Historically, this was one possible way of accounting for the fact that the flux of electron-neutrinos from the Sun is a factor of three smaller than expected. Numerous attempts over the years to detect this flavour mixing — resulting in oscillations, for example in the electron-neutrino flux as a function of distance from a nuclear reactor — have all failed. With the exception of a single Russian experiment on tritium β -decay, the interpretation of which is open to question, all results to date are consistent with zero mass neutrinos and zero mixing. Four articles in the volume are devoted to recent results on double β -decay (setting upper limits on the neutrino mass) and on oscillation experiments at reactors and accelerators.

A third major prediction of GUTs is the existence of magnetic monopoles. These were originally invented by Dirac over 50 years ago, as a way of "explaining" quantization of electric charge. In GUTs however, the charge quantization follows from the construction of the theory, and the result is that massive elementary monopoles, of mass 10^{16} GeV or 10^{-8} g, absolutely have to exist. In the original big bang model of the Universe, enormous numbers of monopoles would be predicted. A free bonus of the "inflationary

The X-ray flux of the bright galactic bulge source GX5-1 shows intensity-dependent quasi-periodic oscillations between ~20 and ~40 Hz, appearing as a broad peak in the power spectrum whose centroid frequency, width and integrated excess power strongly depend on the source intensity. The strength and steepness of low-frequency noise present in the power spectra below 15 Hz also depend on the source intensity. No evidence is found for coherent X-ray pulsations between 0.5 and 2,000 Hz. We discuss possible mechanisms to explain these new phenomena.

NEUTRON stars in low-mass X-ray binaries have long been suspected to have been spun up to periods in the millisecond range. Several searches for such short rotation periods in low-mass X-ray binaries have been made but none has been successful (refs 1-4 and J. Fleischman, S. Rappaport, D. Strahs and W. Lewin, personal communication). We have renewed the search using the medium energy detectors of the X-ray observatory Exosat. One of the first sources we observed was the bright bulge source GX5-1, in which we found no periodic pulsations but, unexpectedly, we discovered quasi-periodic oscillations. These oscillations are the subject of this report; some preliminary results have already been reported⁵.

Observations

We observed GX5-1 (4U 1758-25) with the medium-energy detector⁶ (ME) and the gas scintillation proportional counter⁷ on Exosat. The observations started on 18 September 1984 11:50 UT and lasted for ~8 h. We shall discuss 1-18-keV data obtained with the Ar/CO₂-filled proportional counters of the medium-energy detector; the counters were co-aligned with a total effective area of 1,500 cm². The data were obtained in 2-s blocks, each containing 8,192 samples (time resolution ~0.25 ms). Within each of the 1,623 blocks, the data are continuous with a negligible 'dead time' of ~1% and between two consecutive data blocks there is a gap of 15 s. The data contain no spectral information.

Figure 1 shows the counting rate as a function of time. The data include an approximately constant background of ~80 c.p.s. The sharp drop near $t = 17,000$ s is caused by a change ('trim') in the satellite pointing direction. The reason for this trim was the high counting rate, at which detector damage was feared. Before the trim, the collimator efficiency was 93%, whereas afterwards it was 65%.

For the average spectral shape, as measured with the gas scintillation proportional counter, 1 c.p.s. from the ME (pre-trim collimator efficiency) corresponds to $\sim 9.2 \times 10^{-12}$ erg cm⁻² s⁻¹ (1-18 keV), or ~ 0.3 μ Jy (2-11 keV). The source flux (~ 700 - $\sim 1,100$ μ Jy) and its variability on a timescale of hours are similar to those encountered previously⁸⁻¹². All count rates described here have been reduced to the pre-trim collimator efficiency.

Analysis and results

To investigate the variability of GX5-1 on timescales between 0.5 ms and 2 s, we estimated the power spectrum by calculating (via a fast Fourier transform (FFT) algorithm) the Fourier amplitudes of the average-subtracted signal in each 2-s block

Fig. 1 Average counting rates in 2-s time intervals. Zero time corresponds to 18 September 1984, 11:53:35 UT. The sharp drop near $\sim 17,000$ s is the result of a change in the pointing direction of the satellite (see text).

separately. The power spectra of single data blocks are too noisy to allow meaningful study. However, the average of these power spectra clearly shows three components: (1) low-frequency noise below 15 Hz (the power increases towards lower frequencies); (2) a strong broad peak with a centroid frequency near 30 Hz; and (3) a flat spectrum above 100 Hz, consistent with Poisson noise.

No evidence was found for coherent pulsations in the X-ray flux. The 99% confidence upper limit to the pulsed fraction of coherent pulsations in the 50-400-Hz range is 0.3%; in the 400-2,000-Hz range it varies between 0.6 and 2.5%, depending on frequency. In calculating these values, we followed the procedures described by Leahy *et al.*³ and took into account possible Doppler shifts resulting from orbital motion of the source and the satellite.

Power density estimates, using conventional FFT techniques, may be in error because of low-frequency 'leakage', if a steep low-frequency ('red') noise component is present¹³. The power-law slope of the red noise in our data is considerably below the critical value of 2, above which problems may occur. Low-frequency leakage is therefore not expected to affect our analysis. This was confirmed by tests on artificial red-noise data and by repeating the analysis of the 2-s blocks after 'detrending' each of them by subtracting a low-order polynomial.

The properties of the broad peak in the power spectrum (centroid frequency, width and integrated excess power) and the low-frequency noise (slope, and integrated excess power) strongly depend on source intensity. In Fig. 2a, b we show the

observed power spectra as a function of time and source intensity, respectively. The broad peaks in the power spectra are seen in Fig. 2a as a dark 'ribbon'; the low-frequency noise is visible at the bottom. The centroid frequency ν_c is clearly correlated with the source intensity (Fig. 2a). Also, both the quasi-periodic oscillations and the low-frequency noise diminish at high source intensity. The dependence of ν_c on source intensity is approximately linear (Fig. 2b). This dependence is not affected by the $\sim 30\%$ drop in counting rate caused by the 'trim' near $t = 17,000$ s (Fig. 1). A power-law dependence, however, is also consistent with the data.

The fact that ν_c depends on source intensity and not on the counting rate in the instrument convinced us that the peak in the power spectrum is related to a phenomenon in GX5-1 and is not an instrumental effect or an artefact of the analysis. In this context we mention that background data obtained immediately before and after our observation with the same time resolution, and observations of several other sources of similar brightness, did not show a peak in the power spectrum.

As far as we can tell at this stage of the analysis, all variable properties of the power spectra depend on the source intensity only. To describe the power spectra quantitatively, we performed least-squares-fits to the averages of power spectra selected from six source-intensity intervals. As a fitting function we used

$$P(\nu) = A + B e^{-\gamma\nu} + C[(\nu - \nu_c)^2 + (\lambda/2)^2]^{-1} \quad (1)$$

where P is the power density and B and C are normalization constants. The first term on the right-hand side (a constant) describes the white-noise component. In our adopted normalization³ one expects $A = 2$ for poissonian noise. The low-frequency noise is well described by an exponential function (second term in equation (1)). A power law does not adequately fit the data.

We used a Lorentz profile with a full-width at half maximum, λ , and centroid frequency ν_c (third term in equation (1)) to describe the peak. We also tried to fit the peak with a gaussian profile; this did not give better power-law fits to the low-frequency data. (The width and integrated excess power of the peak are then 20–30% lower.)

The fits of expression (1) to the averaged power spectra (first 512 frequencies) have a reduced χ^2 between 1.03 and 1.17 for 506 degrees of freedom. The variance of the power estimates was taken as $4/N$, N being the number of power spectra averaged³. Examples of the fits are shown in Figs 3 and 4. For decreasing source intensity, ν_c decreases, the peak becomes narrower and the low-frequency noise component steepens.

Figure 5 shows plots of the numerical results (listed in Table 1). The centroid frequency of the peak (Fig. 5a) shows a strong, approximately linear correlation with source intensity. The peak width (Fig. 5b) and the steepness of the low-frequency noise spectrum (Fig. 5c) show an approximately monotonic dependence on the source intensity. The integrated excess power of both the peak (Fig. 5d) and the low-frequency noise (Fig. 5e) show a maximum, roughly halfway in the observed intensity range.

The width and integrated excess power of the peak are 30–50% lower than shown in Fig. 5 (b, d) if we choose a power-law description of the low-frequency noise (both for a lorentzian and a gaussian peak profile). The centroid frequency is very insensitive to changes in the fitting function.

In principle, the broad peaks in the averaged power spectra could result from the averaging out of very narrow peaks which occur at different frequencies in the power spectra of the individual 2-s data blocks. However, the peak remains broad when the data are analysed in intervals as short as ~ 100 s.

We shall assume that the averaged power spectra are representative of those of the individual 2-s blocks. The results can then be interpreted as resulting from a signal that shows quasi-periodic oscillations of which the typical period decreases from 50 to 25 ms and the coherence time (defined as the e folding time of autocorrelation function) from 75 to 25 ms when the source intensity increases by $\sim 30\%$. The signal also contains low-frequency noise to which the contribution of slower vari-

Fig. 2 a, Display of the temporal variation of the power spectra. The frequency is in the vertical direction (left-hand scale). A vertical cross-section of the display is a grey-scale coded representation of a power spectrum. The darker the shade the higher the power it represents. To conserve the quality of the picture, the original display of 512×512 pixels has been smoothed with a gaussian profile with $\sigma = 1.3$ pixels. The variable broad peak in the power spectra is visible as a dark 'ribbon'; the low-frequency noise is visible at the bottom. Also shown is the intensity of GX5-1 (right-hand scale). The peak frequency depends strongly on source intensity. Also, notice that both the quasi-periodic oscillations and the low-frequency noise diminish at high source intensity. b, Display (see a) of the power spectra as a function of source intensity (reduced to pre-trim collimator efficiency). The peak frequency is approximately linearly related to source intensity.

ations becomes weaker for increasing source intensity and of which the strength (integrated excess power) depends on the source intensity in a way very similar to that of the peak.

The noise process that underlies the quasi-periodic character of these oscillations is not strongly constrained by our present analysis; the counting rates are too low to allow us to follow individual wave trains. It could be the result of (see, for example, ref. 14): (1) a superposition of randomly excited damped harmonic oscillators; (2) random phase variations of a periodic wave train; (3) the superposition of closely spaced periodic oscillations whose frequencies are distributed over a finite interval. It is also conceivable that the broad peak is the result of a dependence of the peak frequency on the X-ray photon energy, which is smeared out because of the absence of energy resolution in our data.

Discussion

Intensity-dependent quasi-periodic oscillations, such as those reported here, have not been observed previously (millisecond X-ray oscillations lasting of the order of 10 s have been reported^{2,15} which are probably unrelated). The variations in frequency of the oscillations clearly exclude the possibility that

Fig. 3 Linear displays of average power spectra of GX5-1 in six different source-intensity intervals. *a*, 2,277–2,486; *b*, 2,486–2,695; *c*, 2,695–2,904; *d*, 2,904–3,113; *e*, 3,113–3,322; *f*, 3,322–3,531 (c.p.s.). The average has been taken over the power spectra of individual 2-s intervals (see text). Fits of equation (1) to the data are also shown. Notice the change of centroid frequency and width of the peak as a function of source intensity.

they represent the rotation period of the compact object.

Quasi-periodic oscillations on timescales of the order of tens of seconds are a common phenomenon in cataclysmic variables^{14,16,17}. Of particular interest are the optical oscillations seen during some dwarf-nova outbursts which show a positive correlation between frequency and (optical) flux^{14,18,19}. Apart from the $\sim 10^3$ times longer period and the different energy band, these oscillations differ from those in GX5-1 by: (1) the generally one to three orders of magnitude larger coherence; (2) the

positive correlation between coherence time and source intensity¹⁹ (negative in GX5-1, see Figs 3, 4, 5*b*); and (3) the much weaker dependence of frequency on optical flux.

Models proposed for these dwarf-nova oscillations include inhomogeneities rotating with the inner accretion disk^{20,21}, or with the white dwarf envelope²²; disk oscillations^{23,24}; oscillations in the atmosphere of the white dwarf^{25,26}; and various instabilities in the accretion flow (for example 27–29; for reviews see refs 14, 18). We examine some of these models in the context of our new findings for GX5-1, assuming that the compact object is a neutron star; in the case of cataclysmic variables the compact object is a white dwarf.

The dependence of the frequency of the oscillations on the source intensity in GX5-1 is strong ($d \log \nu_c / d \log I \sim 2$). The accretion-flow instability models of Langer²⁸ and Livio²⁹ can be excluded on this ground alone. The model of King²², which involves magnetic loops anchored in a differentially rotating envelope of the compact object, predicts the correct sense for the correlation of intensity with frequency and coherence of the oscillations, but does not make quantitative predictions.

Non-radial *g*- or *r*-mode oscillations of the neutron star envelope could have periods in the range observed by us^{30,31}. Proposed excitation mechanisms for these oscillations are thermonuclear flashes³² (see also ref. 33) and sudden accretion events³⁴. However, X-ray bursts have never been observed from GX5-1. It is unclear whether, with a mass-accretion rate varying by $\sim 30\%$, the second mechanism can be considered viable.

In Bath's²⁰ model for dwarf-nova oscillations, the oscillations originate from inhomogeneously distributed matter ('blobs') orbiting the compact object with the Kepler frequency at some preferred radius, in particular that of the magnetosphere, r_m . In the case of spherical accretion, r_m is given by^{35,36}

$$r_m = (2.9 \times 10^8 \text{ cm}) \mu_{30}^{4/7} m^{1/7} R_6^{-2/7} L_{37}^{-2/7} \quad (2)$$

Here μ_{30} is the magnetic moment of the compact object in units of 10^{30} G cm^3 , m its mass in units of solar masses, R_6 its radius in units of 10^6 cm and L_{37} the X-ray luminosity in units of $10^{37} \text{ erg s}^{-1}$. In our further discussion we assume $m = R_6 = 1$.

The keplerian frequency ν_K at the magnetospheric radius depends on the X-ray luminosity according to

$$\nu_K = (0.37 \text{ Hz}) L_{37}^{3/7} \mu_{30}^{-6/7} \quad (3)$$

With $\nu_K \sim 30 \text{ Hz}$ and $L_{37} \sim 10$, one infers $\mu_{30} \sim 2 \times 10^{-2}$ or, equivalently, a surface magnetic field strength $B_0 \sim 2 \times 10^{10} \text{ G}$ and $r_m \sim 160 \text{ km}$. The relation between the frequency of the quasi-periodic oscillations and the luminosity for GX5-1 is qualitatively as predicted by equation (3). However, as mentioned above, the observed value for the exponent is about five times the predicted value of $3/7$, and this may indicate that this model²⁰ is not applicable here. Alternatively, disk oscillations^{23,24} could occur near, for example, the magnetospheric radius. The periods of disk oscillations are of the order of the Kepler periods³⁷; the oscillations would then occur at a radius of $\sim 10^2 \text{ km}$. The quasi-periodic oscillations in the X-ray flux could, for example, be produced by intermittent occultations of the X-ray source by the orbiting blobs or by the oscillating disk.

Warner²¹ suggested that the observed frequency, ν_c , of the dwarf nova oscillations is the beat frequency of the (keplerian) disk frequency, ν_K , at the magnetospheric radius and the rotation frequency, ν_s , of the white dwarf. Alpar and Shaham^{38,39} suggest the same idea to explain the oscillations in GX5-1. For the case of the neutron star this leads to

$$\nu_c = (0.37 \text{ Hz}) \mu_{30}^{-6/7} L_{37}^{3/7} - \nu_s \quad (4)$$

The dependence of ν_c on luminosity can then be made stronger at will by a proper choice of the value of ν_s . A fit of relation (4) to our data (dashed curve in Fig. 5*a*) yields $(\nu_s)^{-1} = 10.5 \pm 0.4 \text{ ms}$ and $B_0 = (6.3 \pm 0.3) \times 10^9 (D/10 \text{ kpc}) \text{ G}$; here D is the source distance. The magnetospheric radius is $\sim 60 \text{ km}$.

The derived magnetic field strength depends strongly on whether the blobs are seen at the magnetospheric radius, r_m (equation (2)), or at some other radius. According to Ghosh and Lamb⁴⁰, for disk accretion, the appropriate magnetospheric

Fig. 4 Logarithmic displays of average power spectra in four different source intensity intervals (see Fig. 3 legend). *a*, 2,277–2,486; *b*, 2,695–2,904; *c*, 2,904–3,113; *d*, 3,113–3,322 (c.p.s.). The dependence of the low-frequency noise on source intensity is seen more clearly than in Fig. 3.

radius is $\sim 0.5 \times r_m$, which would lead to a field three times stronger. However, the above value for ν_s would not change.

A potential problem with models involving a magnetosphere^{20,21,38,39} is the absence in our data of coherent X-ray pulsations, resulting from the neutron star's rotation, with a period near 10 ms (see Fig. 4). The upper limit (99% confidence level) to the pulsed fraction of coherent pulsations with periods in the range from 5 to 20 ms is 0.3%. Compared with a 'classical' X-ray pulsar, for example, HerX-1 ($B_0 \sim 4 \times 10^{12}$ G; ref. 41), the magnetospheric properties of GX5-1 would be very different. The magnetospheric radius would be ~ 50 times smaller, the magnetic dipole field at $r_m \sim 10^2$ times higher, the opening angle of the accretion column near the magnetic pole a factor of ~ 6 larger, the density of the inflowing matter at $r_m \sim 3 \times 10^3$ times larger and the column density outside the magnetosphere $\sim 10^2$ times larger. It is therefore possible that the neutron star in GX5-1 cannot be seen directly because it is obscured by plasma. It is also conceivable that a special geometry of 'X-ray beams' may hide the signature of the neutron star spin, or that the magnetic and rotation axes are co-aligned.

Despite the fact that the beat-frequency model^{21,38,39} has been introduced in a rather *ad-hoc* fashion to account for the observed relation between frequency and intensity, the inferred rotation period and magnetic-field strength of the neutron star fit well³⁸ into an existing evolutionary framework for the galactic bulge sources^{42,43}, which links these objects to the 6-ms radio pulsar⁴⁴ PSR1953+29.

In this evolutionary model^{42,43}, neutron stars in bright galactic bulge sources are spun up to millisecond rotation periods because of accretion from an evolved companion, and the X-ray

sources evolve into wide binary radio pulsars^{45–47}. (That a spun-up neutron star with a relatively weak magnetic field, in a binary, may later on show up as a fast radio pulsar was first suggested by Smarr and Blandford⁴⁸ and further elucidated in refs 49–53.) The rotation period of ~ 10 ms, as predicted by the beat-frequency model for GX5-1, is in accordance with the evolutionary model^{42,43}. The magnetic dipole field strength of PSR1953+29 ($\approx 2 \times 10^{10}$ G; refs 45, 54) is comparable to that predicted by

Results of least-squares fits of equation (1) to averaged power spectra taken from six source-intensity intervals. *N* is the number of individual power spectra (2-s data blocks) averaged, the values for I_{lim} indicate the limits in source intensity defining the intervals, and $\bar{I}$ is the average intensity within each interval. Peak centroid frequency ν_c , full-width at half-maximum λ , steepness parameter γ of the low-frequency noise and the white-noise level A are defined by equation (1). P_{peak} and P_{LFN} are the integrated excess power in the peak and in the low-frequency noise, respectively. These numbers are the integrals ($\nu=0$ to ∞) of the third and the second term, respectively, of the fits of equation (1), to the power spectra, normalized to assign a power a^2 to a sinusoidal modulation with amplitude a . f_{peak} and f_{LFN} are the corresponding relative amplitudes. Quoted errors correspond to the extreme limits of the $\chi^2_{\text{min}} + 1$ error contours.

Fig. 5 Parameters of the power spectra (see Table 1) as a function of source intensity. *a*, Centroid frequency ν_c of the peak in the power spectrum. The dashed curve is a fit of equation (4) to the points. Clearly, a linear relation would also be an excellent fit to our results. *b*, Full-width at half maximum, λ , of the peak in the power spectrum. In this panel the two highest intensity intervals have been combined. *c*, Steepness parameter, γ , of the low-frequency noise. *d*, Integrated excess power of the peak in the power spectrum. Note the striking similarity with *e*. *e*, Integrated excess power of the low-frequency noise. Note the striking similarity with *d*. Vertical error bars are 1σ single-parameter, and take correlations between parameters in the fit into account. Horizontal bars represent the standard deviations of the intensity distributions in each of the six chosen intervals.

the beat-frequency model for the neutron star in GX5-1. These coincidences make the beat-frequency model attractive, but they could well be accidental.

Magnetic fields of neutron stars probably decay on a timescale of $(2-5) \times 10^6$ yr⁵⁵ (but see ref. 56). Therefore, if the quasi-periodic oscillations in GX5-1 are related to a magnetosphere (with a magnetic field strength of the neutron star of the order of 10^{10} G), the age of the neutron star in GX5-1 is probably of the order of 5×10^7 yr. Van den Heuvel and Taam⁵⁷ pointed out that, in the above evolutionary model^{42,43}, neutron stars are most probably formed during the mass-transfer phase by the accretion-induced collapse of a white dwarf. The mass-transfer phase in systems with an evolved companion lasts only $\sim 10^8$ yr. Thus, neutron stars in such systems could be relatively young ($< 10^8$ yr). The mass-transfer phase in systems with low-mass unevolved companions can last up to $\sim 10^9$ yr. Thus in those systems the probability of finding a relatively young neutron star is small. Therefore, if magnetospheric models are correct and the above evolutionary scenario is applicable, one would expect that similar quasi-periodic oscillations in low-mass X-ray binaries may be observed preferentially in systems which have an evolved companion star.

Our data suggest that the low-frequency noise is a different manifestation of the same phenomenon that causes the oscillations (notice the similarity between Fig. 5*d* and *e*). If we speculate that the X-ray oscillations are the result of 'blobs' in the inner accretion disk, the low-frequency noise could perhaps represent the size distribution of the blobs, larger blobs contributing to the noise power at lower frequencies. The blobs would have to disappear when the source intensity is high (decline of low-frequency noise). In this scenario, we can derive a lifetime for the blobs of 0.1–0.2 s from the observed width of the peaks in the power spectra. This estimate is based on the assumption that during its lifetime a blob causes a wavetrain of constant amplitude and frequency. We observe (see Fig. 5*b*, *c*) that when the steepness of the low-frequency noise is at a maximum (many large blobs present), the peak in the power spectrum is relatively narrow (long blob lifetime). This is contrary to what would be expected if this lifetime is dictated by differential keplerian rotation⁵⁸.

Possibly there is a 'gating' mechanism which allows incoming blobs (producing the low-frequency noise) to accrete in a piecemeal fashion (producing the quasi-periodic oscillations). This mechanism could then 'exhaust' the blobs, and now larger blobs may survive longer than smaller ones, consistent with our observations. A gating mechanism would probably fit in any of the above magnetospheric models^{20,21,38}.

Clearly, the scenarios and ideas discussed here are speculative. Any successful model must produce a physical mechanism explaining the observed properties of the quasi-periodic oscillations and the low-frequency noise, including their strong dependence on the source intensity.

We observed GX5-1 again for ~ 8 h on 29 April 1985. An analysis, performed the same day, showed that the quasi-periodic oscillations were again present. When this manuscript was in the final stage of typing, Dr W. Friedhorsky and his co-workers informed us that they observed (personal communication) similar phenomena from ScoX-1 as described here for GX5-1.

We thank France Cordova for helpful comments on an earlier version of this manuscript. M.v.d.K. acknowledges an ESA fellowship, and support during the initial stages of this work from ZWO/ASTRON under contract 19-21-19. The Laboratory for Space Research Leiden is supported financially by the Netherlands Organization for the Advancement of Pure Research (ZWO). W.H.G.L. acknowledges generous support from the Alexander von Humboldt Stiftung and the John Simon Guggenheim Memorial Foundation. W.H.G.L. and J.v.P. thank the directors of the Max-Planck Institute for Extraterrestrial Physics in Garching for their hospitality. This work was also supported by NASA (contract NASS-24441).

Note added in proof: Models for the quasi-periodic oscillations along the lines suggested at the end of this article have been proposed by Alpar, Lamb and Shaham⁵⁹ and by Berman and Stollman⁶⁰. Intensity-dependent quasi-periodic oscillations have also been detected in CygX-2 (Hasinger *et al.*, IAU Circ. 4070), and quasi-oscillations have been demonstrated to be intensity dependent in ScoX-1 (M.v.d.K. *et al.*, IAU Circ. 4068). We point out that CygX-2 has an evolved companion, which supports our suggestion that the oscillations will be preferentially observed in such systems. We thank Fred Lamb for a useful discussion concerning the coherence time of the oscillations.

A highly detailed record of both the direction and intensity of the Earth's magnetic field as it reverses has been obtained from a Miocene volcanic sequence. The transitional field is low in intensity and is typically non-axisymmetric. Geomagnetic impulses corresponding to astonishingly high rates of change of the field sometimes occur, suggesting that liquid velocity within the Earth's core increases during geomagnetic reversals.

THE Steens Mountain (Oregon) reversed-to-normal polarity transition¹ is probably the most detailed record of a reversal of the geomagnetic field reported from a volcanic sequence. This Miocene reversal occurred 15.5 ± 0.3 Myr ago^{2,3} and can be correlated with the older boundary of marine magnetic anomaly 5 B2 (ref. 4). We have completed an extensive palaeomagnetic study of the Steens Mountain reversal to obtain a precise, detailed description of fluctuations in absolute palaeointensity of the geomagnetic field as it reverses. In the course of this study, we also obtained a more complete description of the directional changes during this reversal. These directional and palaeointensity data place new major constraints on the reversing Earth's dynamo.

Field and laboratory methods

We collected slightly over 1,000 oriented samples from three almost completely sampled sections, A, B and C, of the upper two-thirds of the Steens Basalt. Sections A and B are located only 1 km apart on Steens Mountain (42.63° N, 241.43° E) and are readily correlated by matching the transitional field directions. Taken together, these two sections span the end of the pre-transitional reversed period, the transition and the post-transitional normal period. Samples from section C (42.18° N, 240.07° E), located 130 km to the south-west of Steens Mountain, are reversed with the exception of those from the top flow, which display a transitional direction also observed on Steens Mountain¹ at the start of the reversal. The main eruptive centre was probably close to Steens Mountain, and the reversed part of Section C is believed to be older than the reversed zones sampled at the bottom of sections A and B, on the basis of the sequence of palaeomagnetic directions. The composite section obtained by combining sections A, B and C is 615 m thick and consists of ~120 distinct lava flows, which are numbered within each section from the top to the bottom.

The palaeodirection of the field was calculated from the remanence direction after either alternating field or thermal cleaning. After grouping successive flows with the same average direction of remanence, the Steens record consists of 55 directional groups (also numbered from the top to the bottom) of which 12 are reversed, 29 are transitional and 14 are normal (Fig. 1).

The absolute palaeointensity of the field was determined using the method of Thellier and Thellier⁵. Although time-consuming,

this method is preferable because it relies on experimentally well-established physical laws and a sound theoretical background. In addition, the method allows palaeointensities to be determined without the direct heating of samples to high temperatures required by other methods, which usually result in major magnetochemical changes. We selected 185 samples for palaeointensity investigations with low viscosity index, high Curie point and reversibility (or near-reversibility) of the strong-field magnetization curve versus temperature. These criteria proved to be pertinent. We obtained 157 useable palaeointensity values corresponding to 51 vectorial groups (group of successive flows with the same directions and palaeointensities).

Vectorial description

The transitional state of the geomagnetic field vector may be defined as corresponding to successive vectors of which either the directions or intensities (or both) are outside the range of secular variation observed in the adjacent pre- or post-transitional periods. Using this criterion, the end of the transition corresponds to directional group (DG) 15 whose direction and intensity are both transitional (Fig. 2). The beginning of the reversal was recorded by DG 43, which displays the first transitional palaeointensity (Fig. 2). However, the direction of the field at the same time was only 27° away from that of the reversed dipole (Fig. 1) and may be considered to be within the range of secular variation. Thus, transitional palaeointensities seem to have shortly preceded the transitional directions, which were recorded by the immediately following directional groups. In contrast, normal directions and intensities were recovered simultaneously at the end of the reversal.

Records of secular variation before and after the reversal were used to obtain a crude estimate of the duration of the transition. We assumed that these records are essentially complete because of the high extrusion rate needed to record the field reversal in such detail. A review of archaeomagnetic results⁶ shows that the angular rate of change of the virtual geomagnetic pole, when calculated from 2,000 yr BP to the present, is almost the same ($6 \pm 1^\circ$ per 100 yr) for areas as widely separated as Europe, North America and Japan. Assuming that this rate can be used for the Miocene, we found that the reversed and normal records in the Steens Basalt correspond to periods of 5,000 and 3,500 years, respectively. The corresponding accumulation rates of flows at Steens Mountain (sections A and B) are the same (43 ± 4 m per

Fig. 1 The Steens Mountain directional record. Stereographic projection (true angle) of the rotated field direction of the successive directional groups. Directions are rotated by 28.5° about the east-west horizontal axis to bring the dipole field directions coincident with the poles of the projection sphere³⁶. The reversal angle varies from 0° (reversed dipole direction) to 180° (normal dipole direction), and corresponds to lines of equal 'latitude' on the projection sphere. Lines of equal 'longitude' correspond to pseudo-declination, which is measured in the 'equatorial' plane from the projection of the north-seeking direction into this plane. A purely axisymmetrical field would have a pseudo-declination equal to 0 or 180° , which corresponds to near-sided or far-sided¹³ virtual geomagnetic pole paths, respectively. Directional group numbers are indicated near most of the circles representing the successive average field directions. With few exceptions (see Fig. 3), 95% confidence semi-angles are only a few degrees and could not be drawn on this diagram. Full circles and solid path are on the hemisphere of the projection sphere which contains the pole of projection (reversal angle 90° , pseudo-declination 150°); empty circles and broken path are on the opposite hemisphere.

1,000 yr) for the pre- and post-transitional zones, which makes it reasonable to estimate the duration of the reversal from the thickness of the transition zone (190 m). Hence, the transition period lasted $\sim 4,500$ yr, with an uncertainty of $\sim 1,000$ yr.

The pre-transitional reversed period is characterized by an average palaeointensity of $31.5 \pm 8.5 \mu\text{T}$ ($\pm$ s.d.). This mean is $\sim 30\%$ lower than the expected Miocene field at the site, as calculated from 49 independent palaeointensity data from all over the world, obtained using the Thellier method⁷⁻⁹. We interpret this difference, significant at the 95% confidence level, as resulting from a long-term decrease in the dipole intensity before the reversal. The rather large fluctuations of the field direction before the transition (Fig. 1) support the idea of a relative decrease of the dipole with respect to the non-dipole terms before the reversal. This pre-transitional dipole decrease would have lasted at least 5,000 yr.

In contrast, the intensity of the post-transitional normal field ($46.7 \pm 20.1 \mu\text{T}$) is not significantly different from the expected average Miocene field. However, large and apparently rapid intensity fluctuations are observed during this $\sim 3,500$ -yr-long record (Fig. 2), which may reflect some instability of the newly re-established dipole.

The major feature of the Steens Mountain transition is the succession of two distinct phases (Fig. 1). The first phase is a reversed-transitional-normal flip that apparently lasted no more than $\sim 1,500$ yr because of the thickness of the recording zone. The second phase is a normal-transitional-normal 'rebound'¹ which probably lasted twice as long. The apparently brief period of time between these two phases during which normal dipole-like directions occur is marked by an increase in field intensity back to pre-transitional values (Fig. 2). Thus, we interpret these

directions as corresponding to a briefly re-established dipole configuration.

During phases 1 and 2, we found very low values of geomagnetic intensity with several minima close to $5 \mu\text{T}$. The average intensity of the typically transitional field vectors, that is, the 18 vectors directed more than 45° away from the unsigned dipole direction, is $10.9 \pm 4.9 \mu\text{T}$. This is about one-fifth of the intensity of the non-transitional Miocene field. We observe also that the r.m.s. values of the north-south, east-west and vertical components of these transitional vectors are of a comparable order of magnitude with those of the historical non-dipole field at the latitude of the site. Figure 2 shows that there is a fairly regular westward movement of the field vector as the reversal develops, which strongly suggests that at least part of the transitional field is longitudinally drifting.

Transitional geomagnetic impulses

Three large directional jumps are observed during the transition (Fig. 1), amounting to $\sim 90^\circ$ differences between successive pairs of directional groups. This is in marked contrast to most of the Steens Mountain record, where successive angular differences are more often close to $\sim 20^\circ$, suggesting a detailed sampling of the transitional field. Although we first interpreted these jumps as a result of some intermission in the eruptive process, further observations suggested that they instead reflect some large and very rapid changes (geomagnetic impulses) of the field. The most convincing evidence comes from the second impulse, which is recorded in section A from flows A46-A43 (DG 24) to A40-A38 (DG 21). Two lava flows, A42 (DG 23) and then A41 (DG 22), erupted at the beginning of this impulse. After magnetic cleaning, the top and middle of both of these flows possess

distinctly different directions of magnetization (Fig. 3). Considering the chronology of the flows and their directions of remanence, these differences are not caused by reheating by the overlying flow. Field evidence also eliminates differences resulting from volcanological processes such as filling of lava tubes or rotation of magnetized blocks during eruption.

The directions of natural remanent magnetization can sometimes be extremely scattered, even antipodal, within a flow interior because of some secondary chemical remanent magnetization developing after the cooling of the flow¹⁰. In the only such example yet reported, thermal cleaning at high temperature allows the recovery of the direction of primary remanence¹⁰. In contrast, natural remanent magnetization directions in the interior of both flows A41 and A42 are not extremely scattered before or after magnetic cleaning (Fig. 3). The directions of magnetization of the near-surface samples do not change significantly during either alternating field or thermal cleaning. Most of the blocking temperature ranges of these samples are between 500° and 550 °C, whereas the interior samples display a distribution of blocking temperatures between 20 and 600 °C. However, after destroying some secondary magnetization directed towards the present-day field, directions found at high temperatures (~500 °C) in the interior samples are not different from those obtained by alternating field cleaning, and their cleaned directions remain obviously different from those of the near-surface samples (Fig. 3). Thus, the remanence of the interior samples seems to be primary in origin, having been acquired at high temperature during flow cooling.

Therefore, we interpret the distribution of directions observed in flows A42 and A41 as resulting from a geomagnetic impulse occurring during the cooling of these flows. The near-surface directions of flows A42 and A41 yield an average inclination of 45.4°, a declination of 279.5°, with $\alpha_{95} = 3.1^\circ$. This direction differs from the interior average directions of flows A42 and A41 by $16 \pm 11^\circ$ and $34 \pm 13^\circ$, respectively (95% confidence intervals). To estimate the rate of change of the field during the impulse, we need to know the cooling history of the flows. This is only possible for flow A41, which must have acquired its magnetization before being covered by the subsequent flow which has a different magnetization direction. Assuming that the primary remanence was acquired at ~500 °C, and according to temperature measurements in Hawaiian lava lakes¹¹, we find that ~8 months should have elapsed between the time that the top and the middle of this 4-m-thick flow became magnetized. The angular rate of change would have then been $\sim 50 \pm 20^\circ \text{ yr}^{-1}$. The 95% confidence interval given here corresponds only to the uncertainties about directions, neglecting those about the cooling time, which are large but difficult to estimate. Four palaeointensity values were obtained from flows A42 and A41. Their arithmetic average is $7.1 \pm 0.9 \mu\text{T}$, indicating that this impulse occurred when the field intensity was very low. The corresponding rate of change of the field vector during the impulse would have been $6.7 \pm 2.7 \mu\text{T yr}^{-1}$.

There is similar, though qualitative, evidence that the first directional jump (Fig. 2) also corresponds to a geomagnetic impulse. The possibility that the third jump also results from an impulse cannot yet be demonstrated.

General characteristics

Comparison of sedimentary records of the Brunhes–Matuyama reversal obtained from various locations on the globe indicates that the transitional field is not dipolar^{12,13}, insofar as the reversing field is faithfully recorded in the rocks studied. To describe the transitional fields in more detail, one has to turn to volcanic rocks, which are much more reliable recorders of both the direction and intensity of the field. Indeed, only volcanic rocks allow the determination of both the 'instantaneous' field direction and absolute palaeointensity. A consideration of the new data from the Steens Mountain reversal together with other data from transitions recorded in Cenozoic volcanic sequences confirms that transitional fields are low in intensity and suggests that these fields have three other major characteristics: import-

Fig. 2 The Steens Mountain vectorial record, showing average inclination, declination and intensity (logarithmic scale) of the geomagnetic field calculated for groups of successive lava flows which do not differ significantly in direction or intensity. *a*, *b*, 65 data points, some of which correspond to subdivisions of the directional groups within which intensity varies significantly between successive lava flows. *c*, 51 data points corresponding to the vectorial groups defined in the text. Group numbers 15 and 43 are indicated by the representative points. Average values are plotted versus thickness from the top of section A (2,950 m), so that time develops from the left to the right on the diagrams. No samples were collected between 410 and 560 m from the top. Error bars in *c* are s.e.m.; no bar indicates a single intensity determination. Uncertainties about inclination and declination are too small to be represented.

ance of non-zonal terms; occurrence of rapidly dumped oscillations; and geomagnetic impulses.

The Steens Mountain data confirm that palaeointensity of the geomagnetic field is low during reversals and suggest that a long-term dipole decrease precedes the transition. We did not find any evidence of the large intensity value thought to occur at the start of the first phase of the transition¹⁴. To what extent the average intensity of transitional fields found at Steens Mountain (~11 μT , or 20% of the non-transitional intensity) is typical is unknown because there are no comparable studies. Note that the average palaeointensity calculated from Cenozoic field reversals and excursions recorded in volcanic sequences from Iceland is only $5.5 \pm 3.1 \mu\text{T}$ (ref. 15), which suggests that average transitional palaeointensities are latitude dependent.

The importance of non-zonal components during the Steens Mountain reversal can be qualitatively understood from Fig. 1. Only sectorial or tesseral spherical harmonics can account for any deflection of the field direction from the north–south vertical plane (corresponding to pseudodeclination of 0 or 180° in Fig. 1). The second phase of the transition, which is also the longest, exhibits the directions that are the farthest from the geographical meridian. Considering the transition as a whole, the vector density of typically transitional directions (that is, $>45^\circ$ away from the unsigned dipole direction) is at a maximum for angular deviations between 30 and 40° from the geographical meridian (Fig. 4). Thus, most of the Steens Mountain transition is not

Fig. 3 Lambert equal-area projection of the cleaned directions of remanence of individual samples from lava flows A41 and A42, which erupted during the second geomagnetic impulse, and average directions of some pre- and post-impulse lava flows. Average directions are indicated by crosses with the corresponding α_{95} circles: solid circles, flows A41 and A42; broken circles, pre- and post-impulse lava flows. The pre-impulse directional path (broken line) is recorded successively by flows A48, A47, A46 to A43 and the tops of flows A41 and A42. Two successive records of the field direction during the impulse are provided by the interiors of flows A42 and A41. The post-impulse field direction is recorded by the overlying lava flows A40 to A38.

axisymmetrical, which is a general characteristic of Cenozoic reversals (Fig. 4). As well as the Steens Mountain reversal, data from the 71 directional groups in Fig. 4 correspond to transitions recorded by volcanic sequences in North America¹⁶⁻²⁰, Iceland^{21,22}, Japan²³ and Africa²⁴. Vector density is at a maximum for angular deviations between 40 and 70° from the geographical meridian, in marked contrast to the distribution of non-transitional field directions which would have typically displayed a maximum for a deviation of zero. The observed distribution indicates that, on average, east-west (non-zonal) components of transitional fields are at least as important as the components lying within the geographical meridian. As the latter components are a combination of zonal and non-zonal terms, this suggests that zonal and non-zonal components of transitional fields are of the same order of magnitude.

Thus, during polarity transitions, the geomagnetic field not only loses its dipolar morphology but also its axisymmetry. Similarly, the present-day non-dipole field does not show any predominance of zonal terms. The absence of a purely zonal morphology for transitional fields is compatible with the sugges-

Fig. 4 Histogram showing vector density versus deviation from the geographical meridian for 71 transitional directions from Cenozoic reversals recorded by volcanic sequences (see text). All transitional directions considered are flow or directional group averages which are more than 45° away from the dipole field direction at the sampling site. Vector density is calculated using one as the value of the area on the sphere corresponding to the 40-50° range in deviation from the meridian. Black columns, data from the Steens Mountain transition.

tion that the frozen-flux approximation is valid during reversals²⁵. However, this agreement does not imply that flux diffusion is negligible over the full time of a reversal. In particular, the beginning of the Steens Mountain reversal, which seems to be only moderately non-zonal (Fig. 1), could result from ohmic decay within a geodynamo temporarily inoperative as a consequence of the axial symmetry²⁶.

The notion that the transitional state of the geodynamo corresponds to an oscillating field was proposed by Braginsky²⁷. In contrast, more recent models suppose that the field reverses in a progressive way, through either some spreading of the reversal over the core surface^{13,28} or by reversible energy transfer from the dipole to non-dipole terms²⁹. The entire directional path observed during the Steens Mountain transition can be interpreted as corresponding to a rapidly damped oscillation of the field. Although other records of reversals by volcanic rocks are not as detailed as the Steens Mountain record, examples have been reported in which the field reverses polarity and then comes back to its initial polarity before reversing again, even in such incomplete records^{19,30}. Such observations favour models of the geodynamo that allow a highly damped oscillatory state of the geomagnetic field during reversals.

The geomagnetic impulses occurring during the Steens Mountain transition can be considered as impulses of the first order time-derivative of the field. They may be interpreted as large and possibly global changes of the field configuration with time constants of the order of 1-2 yr. By comparison, we note that the same order of magnitude has been proposed recently for the smoothing time of the 1969 impulse resulting from filtering by the mantle³¹. The rates of change of the field components during the Steens Mountain transitional impulses would have been very large. For the second impulse, the rates of change of the three components would have been between 15 and 50 times larger than the maximum rates calculated for the historical non-dipole field³².

Obviously diffusion of field lines cannot explain such rapid changes; even for harmonic degrees as large as 10, the decay time is still equal to a few hundred years³³. Larger-degree harmonics with decay times of the order of a few years require implausibly large fields at the core-mantle boundary. Under the frozen-flux approximation, however, the transitional geomagnetic impulses can be accounted for by a large increase in fluid velocity at the core surface. This suggests an increase in the level of turbulence within the liquid core during reversals. This increase in kinetic energy can be of thermal origin, resulting from too steep a thermal gradient within the core for a convective

regime to be preserved³⁴. Alternatively, this increase can result from a decrease in magnetic energy. We have shown that, on average, the intensity of the geomagnetic field at the Earth's surface reduces to one-fifth of its normal value during the Steens

Mountain polarity transition. If the field intensity within the core also decreases during reversals, the liquid can become more unstable as part of the magnetic energy is transferred into kinetic energy³⁵.

† Department of Biology, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA

The amino-acid sequence of murine band 3, deduced from the nucleotide sequence of a complementary DNA clone, confirms that this integral membrane glycoprotein is composed of two major structural domains which correlate with its dual functions as the anchor for the erythrocyte cytoskeleton and as a plasma membrane anion antiporter. This latter activity resides within a highly hydrophobic domain that crosses the plasma membrane at least 12 times.

BAND 3 is the major integral membrane glycoprotein of the mammalian erythrocyte¹. It functions as an anion antiporter, mediating the one-for-one, obligatory and electroneutral exchange of chloride and bicarbonate across the plasma membrane (see refs 2-6 for review). This rapid process ($t_{1/2}$ = 40-60 ms), catalysed by the ~1,000,000 molecules of band 3 per erythrocyte³, increases the capacity of the blood to transport CO₂ from the respiring tissues to the lungs. Through its tight association with ankyrin^{7,8}, band 3 anchors the mesh-like cytoskeletal network of spectrin and ankyrin to the inner surface of the erythrocyte plasma membrane (see ref. 9 for review).

As a consequence of its physiological importance and relative abundance, band 3 structure and membrane topology have been characterized extensively by biochemical techniques including proteolytic mapping, inhibitor binding and covalent modification (see ref. 4 for review). Band 3, 929 amino acids long, has two distinct structural domains, one containing the anion exchange activity and the other involved in cytoskeletal interactions.

The ~400 N-terminal amino acids of band 3 are hydrophilic and face the cytoplasm. This negatively charged domain possesses the high-affinity binding sites for ankyrin⁸ as well as, in human band 3, haemoglobin¹⁰ and several glycolytic enzymes^{11,12}. Removal of the cytoplasmic domain of band 3 by proteolytic cleavage of erythrocyte ghosts results in no loss of anion transport activity¹³, demonstrating that this function resides entirely within the C-terminal ~500 amino acids of the protein. Studies on the topology of this domain suggest that it traverses the membrane at least seven times^{14,15}; hitherto it has

only been possible to obtain the sequence of small fragments of this region in the human protein.

Here we report the isolation and the sequence of cDNA clones encoding the full length of murine band 3 messenger RNA. This is the first plasma-membrane anion transporter to be sequenced. Previous studies have established that human and murine band 3 have very similar sizes and biochemical properties¹⁶. We propose a model for band 3 topology that incorporates data from many biochemical and physiological studies.

Isolation of cDNA clones

In mice, anaemic stress induces proliferation in the spleen of erythroid precursor cells that actively synthesize erythrocyte proteins^{17,18}. Polyadenylated RNA from these spleens was used to construct a cDNA library in the expression vector λ gt11 (ref. 19). We screened this library with a polyclonal antibody²⁰ against purified mouse erythrocyte band 3, initially revealing several positive clones, the inserts from which hybridized to each other and to a 4,300-nucleotide mRNA in total spleen RNA (data not shown). The longest of these, pB33, contains a 1,800-base-pair (bp) insert, which was shown subsequently to encompass only ~280 bp of the C-terminal protein coding region, but which extends throughout the entire 3' untranslated region (1,500 bp). We used pB33 as a hybridization probe to screen a second cDNA library, constructed to optimize the yield of full-length transcripts (see Fig. 1 legend). Sequencing the longest insert (clone pB399; 2.7 kilobases (kb)), revealed that it did not contain the N-terminus of native band 3, judged by the homology of the deduced amino-acid sequence with that of the N-terminus

[illegible]

Fig. 1 Composite nucleotide sequence of the cDNA corresponding to mouse band 3 mRNA showing the deduced amino-acid sequence. Nucleotide numbers are indicated in the right-hand margin and the sequence is written with the 5' end of the cDNA at the top left. Position 1 is the ATG triplet which is the probable start of the polypeptide. The in-frame nonsense codon at base -63 and an out-of-frame ATG at -50 are underlined. The two potential glycosylation sites at (611 and 660) are designated by boxes. The 15 tandem repeats of the tetranucleotide ATTC at nucleotide positions 3,490-3,550 in the non-translated region and the polyadenylation signal at base 4,232 are underlined.

Methods. Molecular cloning of mouse band 3. Total poly(A)⁺ RNA was isolated from fresh spleens of severely anaemic BALB/c mice by homogenization in 5 M guanidinium isothiocyanate, purification by ultracentrifugation through a CsCl gradient³⁷ and affinity chromatography on oligo(dT) cellulose³⁸ of this RNA, 10 µg was used to construct a cDNA library in the bacteriophage expression vector λgt11¹⁹ as described previously³⁸, except that the endogenous *EcoRI* sites were not protected with *EcoRI* methylase. A polyclonal rabbit antibody against mouse erythrocyte band 3 (ref. 16) was used in conjunction with ¹²⁵I-labelled protein A to screen⁴⁰ 10⁶ recombinant phage plaques. Fifteen antibody-positive clones were identified and subcloned into the plasmid vector, pUC13⁴¹. pB33 contains an 1,800-bp insert, the longest clone isolated from this library. The *EcoRI* fragment containing the entire pB33 insert was purified by agarose gel electrophoresis and labelled with [α-³²P]dCTP by nick-translation⁴². This was used to probe a second mouse spleen λgt11 cDNA library, which was made as follows: 10 µg poly(A)⁺ RNA was used to synthesize double-stranded cDNA essentially as described by Gubler et al.⁴³ This cDNA was treated with *EcoRI* methylase³⁹ and size-selected by agarose gel electrophoresis to exclude fragments <2.5 kb in length. Of the recombinant phage in this library, 1% contained inserts 3.5 to 4.3 kb long which hybridized to the pB33 insert. pB399 is a pUC13 subclone of the longest isolate obtained from this library. pB3SP4 is a pSP65 subclone⁴⁴ of the longest isolate obtained by screening the library with a 500-bp fragment *EcoRI*/PvuII from the 5' end of pB399. DNA sequencing. Three 200-bp fragments of pB3SP4 were sequenced by chemical cleavage⁴⁵ of DNA fragments end-labelled with [α-³²P]-nucleotides using the Klenow fragment of DNA polymerase⁴². All other sequences were obtained by subcloning cDNA fragments into M13 and sequencing by the dideoxy chain-termination method⁴⁶ using [α-³⁵S]dATP⁴⁷. These fragments were obtained by progressive *Bal31* deletion⁴⁸ in the case of pB33, or by random fragments generated by sonication for pB399 and pB3SP4. *Bal31* digestions were performed as follows: 25 µg plasmid was digested to completion with *NarI*, which cuts pB33 at a unique site 175 bp from the 3' end of the band 3 insert. The linearized DNA was digested with *Bal31* (New England-Biolabs) for 24 min at 30 °C using a concentration of 1 U *Bal31* per µg DNA. Aliquots of the reaction mixture were removed at 3-min intervals. Following ethanol precipitation, the DNA was digested with *EcoRI* and ligated with M13 mp8⁵⁰ RF DNA digested previously with *EcoRI* and *SmaI*. Preparation of cDNA fragments for sonication was as follows: 5 µg gel-purified restriction fragment was self-ligated and sonicated⁴⁹; the ends were repaired by treatment of the fragments with T₄ polymerase in the presence of 0.1 mM deoxynucleoside triphosphates. The resulting DNA was fractionated on a 1.5% agarose gel. The eluted fragments were ligated with *SmaI*-cut M13 mp18 RF DNA. All transformations were done with *Escherichia coli* JM103 (ref. 50) as described previously⁴². The entire sequence was assembled using the DB programs of Staden⁵¹. The database contains 174 gel readings, representing an average nucleotide redundancy of 5. The entire sequence has been obtained for both strands.

Fig. 2 Alignment of sequences of fragments of human band 3 with the deduced sequence of the mouse protein. The ALIGN program of Dayhoff *et al.*⁵² was used to obtain the optimal alignment using the mutation data matrix⁵². Shown are the alignments for an N-terminal fragment, H1 (ref. 21), a short peptide from the N-terminus of a M_r 14,000 chymotryptic fragment, H2 (ref. 25), and two fragments from the membrane-associated domain, H3 (ref. 25) and H4 (ref. 26). Boxes indicate amino acid identity between the two species. The alignment scores were compared with those obtained from 150 randomizations of the entire mouse sequence, using a break penalty of 2. The scores for the alignments were 14.6 (H1), 2.66 (H2), 15.5 (H3) and 12.2 (H4) standard deviations, respectively.

of human erythrocyte band 3 (ref. 21; see below). Therefore, we re-screened the library using a 5' fragment of pB399 as a probe, and isolated a cDNA clone, pB3SP4, encompassing 127 bp of 5' untranslated region as well as the entire 2,900-bp open reading frame encoding murine band 3.

Band 3 sequence homology

The complete sequence of 4,383 nucleotides compiled from the cDNA clones pB33, pB399 and pB3SP4 is shown in Fig. 1. The size of the full-length cDNA represented by the three clones agrees well with that of the mRNA (data not shown). The overlapping regions of the three clones have identical sequences. A single open reading frame extends for 929 codons from the ATG at nucleotide 1 to the TGA at base 2,919. There are two in-frame ATG codons at the beginning of the open reading frame (residues 1 and 4). We have assigned the first Met codon as the initiator because it is the first in-frame ATG downstream of the (in phase) stop codon at base -63. The sequences flanking this ATG, but not the other one, are homologous to the highly conserved sequence that flanks functional initiation sites in eukaryotic mRNAs: AXX AUG G²². The relative molecular mass (M_r) of the predicted polypeptide is 103,000, in good agreement with estimates of 90,000–100,000 obtained from SDS-polyacrylamide electrophoresis of the native human¹ and murine²³ proteins. The predicted C-terminal amino acid of the murine sequence is valine, which is also the C-terminal residue of the human protein²⁴. Indeed, of the 12 C-terminal residues predicted from the mouse cDNA sequence, 11 are identical with those determined by carboxypeptidase-Y digestion of human band 3 (R. Reithmeier, personal communication). Parts of the the amino-acid sequence deduced from the cDNA sequence contain high homology to that of the several known fragments of human erythrocyte band 3 (Fig. 2), proving that the clones we have isolated encode the murine erythrocyte anion exchange protein.

The most striking homology is between residues 455 and 492 of murine band 3 and the 38-amino-acid fragment from the human protein designated H3 (ref. 25) in Fig. 2. There is only a single conservative (Leu → Val) substitution between the two sequences; there are no insertions or deletions. Excellent alignment is also observed between the deduced sequence of murine band 3 and the sequence of a peptic fragment (P5) of the human protein designated H4 (ref. 26; Fig. 2); only 10 of the 72 residues differ and alignment of the sequences required no insertions or

deletions. The sequence of the N-terminal 201 residues of human band 3 (ref. 21), designated H1, exhibits a slightly lower homology with the sequence deduced from the murine band 3 clone.

Structural domains of band 3

A hydropathy plot²⁷ (Fig. 3) reveals that murine band 3 can be roughly divided into three domains. The N-terminal 420 residues constitute the hydrophilic cytoplasmic domain with a negative net charge (65 acidic and 37 basic residues). The central 450 amino acids are predominantly amphipathic, and are intimately associated with plasma membrane lipid. In this domain, groups of hydrophobic residues, which correspond to the peaks *a–j* in Fig. 3, are interspersed with polar, predominantly basic, residues, depicted schematically in Fig. 4. The extreme 32 C-terminal residues of band 3 may constitute a third domain. Eleven of these are either Glu or Asp, making it unlikely that the C-terminus is buried within the lipid bilayer.

Cytoplasmic domain

The binding of haemoglobin¹⁰ and glycolytic enzymes^{11,12} to the cytoplasmic domain of human band 3 is mediated by the first 11 residues of the band 3 polypeptide²⁸. The apparent absence of glyceraldehyde 3-phosphate dehydrogenase from mouse erythrocyte ghost preparations (V. Patel, personal communication) is consistent with the lack of homology between the mouse and human sequences in this N-terminal undecapeptide.

Other features of the cytoplasmic domain are more conserved: both human²⁹ and murine band 3 possess six Cys residues (Fig. 4). Three of the murine band 3 cysteines are in the cytoplasmic domain (CH65), consistent with studies on human band 3 (ref. 29).

Low *et al.*³⁰ propose that the cytoplasmic domain of CH65 is a homodimer with a regulated hinge rich in proline residues. These prolines apparently disrupt the α -helical structure of the polypeptide, rendering it susceptible to proteolysis. Note that these prolines (at positions 161, 188, 201 and 204) are all conserved between human and murine band 3 (compare with Fig. 2); Fig. 4 shows them to be clustered around a trypsin cleavage site at position 194. (Interestingly, two other proline-rich regions in the predicted mouse sequence are found at the known primary sites of intracellular and extracellular proteolysis, between residues 361–368 and 567–586, respectively.)

Fig. 3 Hydropathy plot of the deduced amino-acid sequence of murine band 3 using the algorithm and hydropathy values of Kyte and Doolittle²⁷. Hydrophobicities were averaged over windows of 11 amino acids. The 10 hydrophobic regions are designated a-j.

Between the proposed hinge and a region rich in tryptophan (residues 89–119), also highly conserved, is the purported antigenic region of band 3 (ref. 30). Monospecific polyclonal antibodies against total human band 3 recognize determinants located within a M_r 20,000 fragment of the cytoplasmic domain³¹; this site is sufficiently distant from the N-terminus so that the binding of antibody does not interfere with the binding of haemoglobin³⁰. The region between residues 125–138 contains only 57% homology between human and mouse, whereas the residues flanking it on either side are 90–95% homologous, consistent with the lack of cross-reactivity of anti-human band 3 antisera with the mouse protein and vice-versa²³.

The ankyrin binding site on band 3 has not been identified; Low *et al.* tentatively place it between the hinge region and the immunoglobulin G region, because antibodies against band 3 compete with labelled ankyrin for binding³⁰. The high-affinity ankyrin-binding site is probably conserved among different

species and, perhaps, among different non-erythroid ankyrin-binding proteins.

Membrane-associated domain

The C-terminal half of band 3 contains 10 long hydrophobic stretches (Fig. 3a–j). Regions with hydropathy averages >1.5 are usually tightly associated with lipid, and, in the case of several proteins, span the membrane in an α -helical configuration^{27,32}. Our two-dimensional model indicates that seven of these peaks correspond to sequences of amino acids that span the phospholipid bilayer once (Fig. 3a, c–h) and that two (b, i), and possibly a third (j), span twice.

Peaks a, c, e, g and h, designated single-spanning regions 1, 4, 6, 8 and 9, respectively, correspond to continuous stretches of 20–24 extremely hydrophobic amino-acid residues and fit the criteria for forming membrane-traversing α -helices^{27,32}.

Chymotryptic digestion of intact erythrocytes cleaves band 3 into a carboxy-terminal glycosylated peptide, CH35, and an amino-terminal non-glycosylated CH65 (Fig. 4). Sequence data on the N-terminus of human CH35 (ref. 26) positions this site between the putative membrane-spanning segments 5 and 6, thus this segment must be extracytoplasmic. The extensive homology between the amino-acid sequences of murine and human band 3 in the peptic fragment studied by Brock *et al.*²⁶ allows us to assign the topological asymmetry to the corresponding membrane-spanning segments 5–8 of the mouse sequence. Of the two potential sites (Asn-X-Ser/Thr) for attachment of the single N-linked oligosaccharide, the one at residue 611 in the murine sequence corresponds to the site in the human protein²⁶ shown not to contain carbohydrate. Therefore, the site at Asn 660 must be the extracellular attachment site, consistent with the finding that the human Tyr 646 is a substrate for extracellular radioiodination²⁶.

The region encompassing segments 1–5 corresponds to part of the M_r 17,000–22,000 fragment, CH17, generated by chymotryptic digestion of ghosts. It must span the membrane an odd number of times as it results from both an intra- and an extracellular proteolytic cleavage³³. Studies with surface-specific radiolabelling reagents demonstrate that it traverses the bilayer at least three times¹⁵.

Fig. 4 Domain map of band 3. **A**, The scale is the complete amino-acid sequence of murine band 3 deduced from the nucleotide sequence. Probable sites for proteolytic cleavage by trypsin (T) at position 194 (R. Reithmeier, personal communication) and 381 (refs 15, 25), chymotrypsin (C)³³, cyanogen bromide (CN)^{15,25} and papain (P)¹⁴ are indicated. Cysteine residues (SH), binding site for H_2DID s (D), and the known site for exofacial radioiodination (I)²⁶ are all designated. The proposed site for attachment of the N-linked oligosaccharide (CHO) is shown. **B**, Alignment of the fragments from human band 3. The codes H1–H4 are defined in Fig. 2 legend. **C**, Primary fragments arising from digestion of human band 3 with extracellular chymotrypsin, CH65 and CH35^{13,24}; intracellular trypsin, TR41 and TR52²³; extracellular papain, P7 and P25¹⁴; extracellular pepsin, P5^{26,53}; and cyanogen bromide cleavage of CH17, CN6 and CN11^{15,25}. Numbers in parentheses are the actual M_r values of the fragments calculated from their amino-acid composition. These values do not take into account the contribution of the single N-linked oligosaccharide. **D**, Structural features within the N-terminal cytoplasmic domain are: tryptophan-rich (TRP)³⁰, antibody-binding (IgG)^{30,31}, ankyrin-binding (ANK) and hinge are indicated (see text). Locations of the hydrophobic peaks from the hydropathy plot (Fig. 3) are indicated by the letters a–j and the corresponding presumed membrane-spanning regions are designated by the numbers 1–12. Hatched boxes indicate that the region is likely to be amphipathic (see text). **E**, Charge plot. Location of charged residues in the mouse band 3 sequence is indicated by the bar graph, the positions corresponding to the sequence numbers at the top of the figure. The basic residues (Arg and Lys) are assigned a value of +1 while the acidic residues (Glu and Asp) are assigned a value of –1. The bars represent the total (+) or (–) values, above and below the horizontal axis, respectively, over 5 residues.

Fig. 5 Model for band 3 orientation in the plasma membrane. A two-dimensional projection of the orientation of the cytoplasmic domain and the membrane-spanning regions in the lipid bilayer is shown. The sites of oligosaccharide attachment (CHO), H_2DIDS binding, as well as the major extracellular sites of proteolysis, are indicated. Abbreviations are as described in Fig. 4 legend.

If we assume that peaks *a*, *c* and *d* of the hydrophobicity plot correspond to three membrane-spanning segments, 1, 4 and 5, then either region *b* (residues 453–491) does not span the membrane, or it must do so twice. Hydrophobicity peak *b* is quite broad, encompassing 38 moderately apolar residues. These residues can be arranged to form a structure composed of two antiparallel amphipathic helices with Pro 477 forming a turn within the membrane or just at the interface between the bilayer and the cytoplasm. Analysis of the helical amphiphilicity³⁴ suggests that both helices formed by this region of the protein would have all their polar residues projecting from a single face of each helix. Thus, we conclude tentatively that CH17 possesses five membrane-spanning α -helices, of which three (2, 3 and 5) are amphipathic. Helices 1 and 2 could form a hairpin that functions as the internal uncleaved signal sequence²⁰ for insertion of the nascent chain into the endoplasmic reticulum membrane.

Labelling of intact human erythrocytes with a reagent to which the membrane is impermeable has led to the identification of three exofacial lysines in CH17: one on the cyanogen bromide fragment CN6 and two on CN11 (see Fig. 4 and ref. 15). One of the lysines in CN11 binds extracellular 4,4'-diisothiocyanato-2,2'-dihydrostilbene disulphonate (H_2DIDS), a potent inhibitor of anion transport³⁵. Our topological model (Fig. 5) is consistent with these labelling studies, predicting that all three lysines in mouse CH17 (positions 449, 558 and 561) are exofacial. These

data also allow us to assign the site for H_2DIDS binding to either Lys 558 or Lys 561.

Virtually nothing is known about the transmembrane orientation of the C-terminus of band 3 corresponding to hydrophobic peaks *g*–*j*. Our model proposes four or five membrane crossings. The region corresponding to the 43 residues of peak *i* in Fig. 3 resembles membrane spans 2 and 3 in its ability to form an α -helical hairpin in which Arg 800 is situated just at the cytoplasmic surface and the C-terminal 24 amino acids return to the extracellular surface. The proline residues at positions 796 and 802 may be involved in forming the hairpin structure. These two spanning segments, along with segment 12, could form moderately amphipathic helices. Following an extremely polar stretch between residues 832 and 850, there is a short region of 18 mixed hydrophobic and polar residues that forms the N-terminal part of peak *j* in Fig. 3. This is the longest stretch of apolar amino acids between position 850 and the C-terminus of the protein. We propose that this segment spans the membrane once, as an amphipathic α -helix (Fig. 5, segment 12), positioning the C-terminus of the protein inside the cell. Alternatively, the protein may traverse the membrane once more, leaving the C-terminus outside the cell. These two possibilities are shown as dotted lines in the model (Fig. 5).

Analysis of the predicted sequence of murine band 3 reveals that the protein possesses 12 membrane-spanning regions. Five of these are hydrophobic and probably traverse the bilayer as single-spanning α -helices. The seven remaining membrane-spanning regions contain both hydrophobic and polar residues that cross the plasma membrane as amphipathic helical structures, confining their polar and charged side chains to a single face of the helix. These helices, oriented with their axes transverse to the plane of the membrane, could cluster, forming at least one hydrophilic region within the bilayer across which the charged residues involved in the anion-exchange process may pair. Clustering of amphipathic helices round an aqueous 'pore' has been proposed for other transport proteins which span the membrane several times^{32,36}. Significantly, either of the two lysine residues (558 or 561) which bind to stilbene disulphonate inhibitors of anion exchange are associated with such an amphipathic region.

We thank M. Kreitman for assistance with DNA sequencing, S. Alper, R. Doolittle, M. Jennings, J. Kyte, A. Garcia and R. Reithmeier for helpful discussions, and Miriam Boucher for help with the manuscript. This work was supported by grant PO1-HL-27375 from the NIH. Is GX5-1 a millisecond pulsar?

M. Ali Alpar*† & Jacob Shaham†

The bright galactic bulge source GX5-1 (4U1758-250) has recently been observed¹ to exhibit quasi-periods between 25 and 50 ms, with a correlation between the corresponding frequencies f and the count rate I given by $d \log f / d \log I \sim 2.5$. This is the first source observed to exhibit such a phenomenon. We propose here that this behaviour results from fluctuations in accretion rate onto a millisecond pulsar, which has been spun up by accretion to its steady-state spin rate. According to models that use spin-up by accretion to bring the neutron stars to steady-state fast short periods, galactic bulge sources are likely progenitors of millisecond pulsars²⁻¹⁰. After steady state is achieved in these systems, accretion may continue without further spin-up, so that for a substantial fraction of the lifetime of a galactic bulge X-ray source, the neutron star may already be spinning rapidly at the equilibrium spin. The behaviour of GX5-1 can be explained in terms of deviations from this equilibrium state resulting from changes in the accretion rate $\dot{M}$; GX5-1 may, therefore, be a new millisecond pulsar.

For a neutron star of mass M with a dipole magnetic field B_8 (in 10^8 G), radius R_6 (in 10^6 cm) and mass accretion rate $\dot{M}_{17}$ (in 10^{17} g s⁻¹), the Alfvén radius r_A (inner edge of the keplerian accretion disk) is given by

$$r_A = 1.1 \times 10^6 B_8^{4/7} R_6^{12/7} \dot{M}_{17}^{-2/7} (M/M_\odot)^{-1/7} \text{ cm} \quad (1)$$

We have used the normalization of ref. 2 in this equation. The keplerian angular velocity at r_A is

$$\Omega_K(r_A) = (GM)^{1/2} r_A^{-3/2} \\ = 9.5 \times 10^3 B_8^{-6/7} R_6^{-18/7} \dot{M}_{17}^{3/7} (M/M_\odot)^{5/7} \text{ rad s}^{-1} \quad (2)$$

where G is the gravitational constant. Let us denote the equilibrium values of $\dot{M}$ and r_A by $\dot{M}_0$ and r_A^0 . These values determine the equilibrium rotation rate of the star. If $\dot{M}$ deviates slowly from $\dot{M}_0$, the star accretes from the corresponding r_A of equation (1). The specific angular momentum of the accreted matter also varies with this 'instantaneous' r_A ; however, the star's rotation rate will not be affected by such torque variations on time scales much shorter than the spin-up time scale, $\approx 10^7$ yr. Our basic claim is that if the accretion process is controlled by the interaction (matching) between the magnetosphere co-rotating with the star and matter at the instantaneous Alfvén radius, then the luminosity will display a 'beat' frequency¹¹

$$\omega = \Omega_K(r_A) - \Omega_0 \quad (3)$$

in the observer's frame, where Ω_0 is the stellar steady-state angular frequency. The nature of this matching is discussed below.

If the observed X-ray flux originates entirely at the surface of the neutron star, its time dependence is simply that of $\dot{M}$, through $L = G\dot{M}\dot{M}/R$. The luminosity L is related to the observed count rate I by

$$L = 8.1 \times 10^{37} \text{ erg s}^{-1} \left(\frac{d}{10 \text{ kpc}} \right)^2 I(1,000 \text{ c.p.s.}) \quad (4)$$

where d is the distance to GX 5-1. Using equations (2), (3) and (4), we get

$$\omega = a I^{3/7} - \Omega_0 \equiv a(I^{3/7} - I_0^{3/7}) \quad (5)$$

Table 1 Estimated parameters for the neutron star

P_{obs} (ms)	I (1,000 c.p.s.)	r_A (10^6 cm)	$P_K(r_A)$ (ms)	$\Omega_K(r_A)$ (rad s ⁻¹)
25	3.1	4.5	5.20	1,200
50	2.4	4.84	5.84	1,080
	B (10^9 G)	r_A^0 (10^6 cm)	P_0 (ms)	Ω_0 (rad s ⁻¹)
	5.5	5.26	6.6	950

Alfvén radii and keplerian rotation rates corresponding to the observed quasi-periods 25 ms and 50 ms and the rotation period P_0 and magnetic field B are given. These values are obtained from equation (5), with $M = 1 M_\odot$ and $\dot{M}_{17} = 1$

where I is the count rate in 1,000 c.p.s. and a is given by $a = 2.3 \times 10^4 B_8^{-6/7} R_6^{-13/7} (M/M_\odot)^{2/7} (d/10 \text{ kpc})^{6/7}$. From the observed values of $P = 50$ ms at $I = 2,400$ c.p.s. and $P = 25$ ms at $I = 3,100$ c.p.s., we obtain $\Omega_0 = 958 \text{ rad s}^{-1}$, corresponding to a rotation period $P_0 = 6.6$ ms for the neutron star, and $a \approx 745$, which gives $B \approx 5.5 \times 10^9$ G (see Table 1). These are, indeed, typical values for millisecond pulsars^{2,6} spun up by accretion, particularly for those born in bright galactic bulge sources⁶. Note that if the observed frequency is actually the n th harmonic of the fundamental beat frequency²⁰ then the inferred Ω_0 values would be n times smaller, r_A values $n^{2/3}$ times larger and B fields $n^{7/6}$ times larger than the values given in Table 1.

From equation (5), we further find that

$$\alpha = \frac{d \log f}{d \log I} = \frac{d \log \omega}{d \log I} = \frac{3}{7} \frac{1}{1 - \Omega_0/a I^{3/7}} \quad (6)$$

α has the values 2.06 at $I = 3,100$ c.p.s. and 3.70 at $I = 2,400$ c.p.s. The best fit with a constant $\bar{\alpha} \equiv d \log \omega / d \log I$ to the $\omega(I)$ curve, given by equation (5), yields $\bar{\alpha} = 2.68$, in very good agreement with the reported value of ~ 2.5 . Indeed, this is true for any model with a beat frequency given by $\omega = a I^x - \Omega_0$ for $0 \leq x \leq 2.7$. Fitting such models in the observed range 2,400 c.p.s. $\leq I \leq 3,100$ c.p.s., one obtains, for each x , a range of $\alpha(I)$ between ~ 2 and ~ 4 ; this range narrows with increasing x , reaching the single value $\alpha = \bar{\alpha} = 2.7$ at $x = 2.7$, which is the limiting case where $\Omega_0 = 0$ (the neutron star is not rotating).

It is encouraging to find that a whole class of 'kinematic' models that take the observed quasi-period to be beat frequencies, with any rotation rate for the neutron star, can fit the observed α , provided that Ω_K increases with increasing $\dot{M}$. Furthermore, the particular dependence of r_A and of Ω_K on $\dot{M}$, given in equations (1) and (2), or something close to that, must hold very generally¹², as should the relation $L \sim G\dot{M}\dot{M}/R$. If, for example, the observed X rays originated at the instantaneous Alfvén radius, we would have $L \sim G\dot{M}\dot{M}/r_A$. This gives an exponent $x = 1/3$, instead of $3/7$, in equation (5), which then yields $\Omega_0 = 1,285 \text{ rad s}^{-1}$, $P_0 \approx 4.9$ ms and $B \approx 3.6 \times 10^9$ G, values not very different from those obtained with $x = 3/7$. Indeed, all models with $0 \leq x \leq 0.6$ give equilibrium rotation periods $P_0 < 10$ ms for the neutron star. Note that the kinematic model requires $\Omega_K(r_A) > \Omega_0 \equiv \Omega_K(r_A^0)$; hence, the instantaneous Alfvén radii r_A must have been closer to the star than r_A^0 , and $\dot{M}$ must have been larger than $\dot{M}_0$ throughout the observations of the quasi-periodicities in GX 5-1; otherwise, the beat frequency would have been $\omega = \Omega_0 - \Omega_K(r_A^0)$, and negative values of the index α would have been observed.

As an example of a type of physical mechanism that would result in such beat frequencies, we propose a 'magnetic gate' scenario operating through magnetic matching between a field configuration tied to the matter rotating at keplerian velocity at the instantaneous inner boundary of the disk, r_A , and the field configuration co-rotating with the neutron star. We start from an analogy with recent findings concerning the geomagnetosphere and the solar wind. Empirical correlations between magnetic storm and substorm activity in the Earth's magnetosphere

† Present address TBTA Research Institute for Basic Sciences, PK 74, Gebze, Kocaeli, Turkey

and the energy flux from the solar wind entering the magnetosphere were established by Akasofu and Perreault¹³⁻¹⁵. They find that, among many observable parameters of the solar wind, the quantity that correlates with the rate of energy dissipation $u(t)$ in magnetospheric storms is the energy flux into the magnetosphere from the solar wind, $\varepsilon(t)$,

$$\varepsilon(t) = VB^2 L_0^2 \sin^4 \frac{\theta}{2} \quad (7)$$

where V is the wind speed, B is the solar wind magnetic field magnitude at the front of the terrestrial magnetosphere, located at radius L_0 , and θ is the local angle between the solar wind magnetic field and the Earth's magnetic field at that boundary. In equation (7), $L_0^2 \sin^4 \theta/2$ is the effective area through which the external flux enters the magnetosphere. Thus, the flux entering the Earth's magnetosphere is maximum at locations on the boundary where $\theta = \pi$ (ref. 16), where the rate of field line reconnection is presumably maximum. Moreover, the time dependence of this behaviour is not smeared by motions of the plasma. The material flow will thus be enhanced at $\theta = \pi$, and the flow pattern will be modulated by the instantaneous distribution of θ . In particular, if the two flows are simple rotations at different rates, the pattern of relative angles θ will rotate at their frequency difference, and the energy dissipation will be modulated accordingly.

To apply these ideas to the accretion disk, we first note that the energy flux arriving at the boundary is determined by the mass transfer through the keplerian disk. Close to r_A (within a thin boundary region^{17,18}), disk matter is close to pressure balance with the magnetospheric field. Taking $V \cong V_K(r_A) \equiv V_A$, $B^2 \cong 4\pi\rho V_A^2$, $L_0 = r_A$ and $4\pi r_A^2 \beta \rho V_A = \dot{M}$, where β is a dimensionless parameter reflecting the geometry of accretion across the Alfvén surface and ρ is the density of the matter, equation (7) gives

$$L(r_A(t)) = \frac{\sin^4 \frac{\theta}{2}(t)}{\beta} \frac{GMM(t)}{r_A(t)} \quad (8)$$

An average of this quantity over the boundary will determine the influx of matter into the magnetosphere. Thus the observed luminosity will contain some modulation at the beat frequency due to the time dependence in equation (8), through

$$\sin^4 \frac{\theta}{2} = \frac{3}{8} - \frac{1}{2} \cos \theta + \frac{1}{8} \cos 2\theta$$

We now postulate (see ref. 20): (1) that there is some well-defined magnetic field pattern at the boundary r_A^0 ; (2) that this pattern is fixed with respect to the matter rotating at $\Omega_K(r_A^0)$; (3) that it has some finite width Δr around r_A^0 , which we shall call the coherence length. For a non-aligned rotator, θ will generally depend on the azimuthal angle ϕ about the rotation axis of the star and the disk (assumed to coincide), and the only time dependence is rotation at $\Omega_K(r_A^0) = \Omega_0$. As $\dot{M}$ increases and r_A moves inward, pieces of the field pattern move in with the matter and adopt the new keplerian rotation rate $\Omega_K(r_A)$, without substantial smearing. We now have a pattern of θ which is no longer co-rotating with the magnetosphere: the pattern is now rotating at the beat frequency $\Omega_K(r_A) - \Omega_0$ with respect to the magnetospheric field. Hence, a modulation in accretion rate at the beat frequency (or some multiple of it) will appear. This state will be clearly distinct from equilibrium (at r_A^0) once r_A has moved in from r_A^0 by a few Δr . Furthermore, there should also be another memory effect—as r_A moves even further in, the field distribution carried by the matter should lose its coherence altogether.

The above picture can also explain the observed behaviour of the amplitude of the quasi-periodicity. At the lowest frequency observed (that is, when r_A is closest to $r_A^0 > r_A$), 8% of the received flux is quasi-periodic; however, the quasi-periodic fraction decreases with frequency until, at the highest observed frequency (r_A furthest from r_A^0), the quasi-periodic behaviour disappears altogether. We may estimate Δr from the observed

full width at half maximum (FWHM) in the power spectra displaying the quasi-periodicity: $\Delta\omega/\omega \sim 25\%$ gives $\Delta r/r_A^0 \cong 2/3 \Delta\omega/\omega [1 - (r_A/r_A^0)^{3/2}] (r_A/r_A^0) \cong (2-3\%)$. This is consistent with our estimates of the maximum and minimum Alfvén radii involved: $(r_A^0 - r_A^{\max})/r_A^0 \cong 8\%$ and $(r_A^0 - r_A^{\min})/r_A^0 \cong 14\%$ (see Table 1). A coherence time scale for the field pattern to follow radial adjustments to r_A can also be defined as $\tau \equiv \Delta r/V_r$, where V_r is the radial velocity of matter through the disk. This time scale τ must clearly be small compared with the time scale of $\dot{M}$ variations. τ is a measure of the decay time (in the radial direction) of the magnetic field pattern. Thus, if our interpretation of the observation is correct, the observed FWHM $\Delta\omega$ provides a clue to this decay time. Note that it is the instantaneous value of $\dot{M}$ at r_A which gives the correlation; as matter falls in from there rather rapidly, no delay in the correlation is expected.

It is not clear whether the present observations reflect an episode of increasing $\dot{M}$ alone or whether, in the case of decreasing $\dot{M}$ (r_A increasing from r_A^0), the field pattern does not survive coherently. We emphasize that decreasing $\dot{M}$ would give negative values of α , so that observations of negative α would indicate variations in both directions from the equilibrium configuration at r_A^0 . Note that GX5-1 may still be, on the average, spinning up.

One particularly attractive model for realizing the topological discontinuities needed for having the beat-frequency effect is, simply, accretion of magnetized clumps of matter²⁰. As each clump moves across the co-rotation ring at r_A^0 to r_A , it is absorbed in the magnetosphere at the beat rate; absorption of N incoherent clumps only reduces the modulation by $\sqrt{N}$. A logical consequence from such model is red frequency noise in the accretion²⁰. Note, that obscuration and inobservability of the fundamental stellar pulsations at Ω_0 may be here simply due to a thick disk²⁰.

The problems of magnetosphere accretion disk interaction have been discussed extensively (see, for example, refs 12, 17, 18, 19 and references therein). Solutions to particular cases and the difficulties and special assumptions involved testify to the complexity of the problem. Examples of other physical interaction to make the beat frequency observable are discussed in ref. 20 (M.A.A., F. K. Lamb, J.S. and N. Shibazaki, in preparation). On the observational side, further observations of GX5-1 and other galactic bulge sources are of great interest. An observation of a rotation period in the millisecond range as predicted would provide strong support for our kinematic model, but may be elusive in view of the absence so far of any detection of a rotation period and in view of the theoretical picture of galactic bulge sources²¹. One set of past observations, those of the 1,000-s quasi-periodicity in the 8-s pulsating source 4U1626-67²², as well as the 0.5-s quasi-periodicity in the rapid burster²³ and the quasi-periodicity in SCO X-1 (J. Middleditch and W. Friedhorsky, personal communication) may be possible candidates for similar beat frequency effects.

The particular mechanism described above for modulations at the beat frequency may not be unique. A search for similar effects in slow rotators and in massive X-ray sources may give further clues to the differences in the accretion process between these different classes of X-ray sources and will assist in sorting out other possible physical models.

We thank H. Ögelman for bringing the observations to our attention and Michiel van der Klis, F. Lamb, R. Novick, H. Ögelman, N. Shibazaki and J. Trümper for useful discussions. Onset of sublimation in comet P/Halley (1982i)

Susan Wyckoff, R. Mark Wagner, Peter A. Wehinger, David G. Schleicher & Michel C. Festou*

Department of Physics, Arizona State University, Tempe, Arizona 85287, USA

* Institut d'Astrophysique, 98 bis bd Arago, 75014 Paris, France

We report here the first direct evidence for the onset of sublimation of a comet nucleus. Emission due to CN observed in spectra of comet P/Halley (1982i) provides evidence for the development of the gas coma. Broad-band photometric observations of the comet indicate that the dust coma developed near a pre-perihelion heliocentric distance, $r \sim 6$ AU. We have derived rates of gas production and brightening for comet P/Halley at $r \sim 4-6$ AU and use the mean pre-perihelion nuclear magnitude derived for the comet ($r > 8$ AU) to calculate an effective radius of the nucleus (R), which for plausible values of the geometric albedo, $p_v \sim 0.03-0.6$, lies in the range $R = 1-4$ km.

Pre-perihelion spectrophotometric observations (wavelength $\lambda = 3,000-7,000$ Å, $\lambda/\Delta\lambda \sim 250$) covering a heliocentric distance (r) in the range 5.6-4.2 AU of comet P/Halley were obtained using the photon-counting Reticon spectrograph on the 4.5-m Multiple Mirror Telescope (MMT) of the F. L. Whipple Observatory (Table 1). A ratio of the spectrum of comet P/Halley with the solar spectrum is shown in Fig. 1, which provides direct evidence for a gas coma in the comet. The presence of the CN emission band (3,883 Å) is evident in the comet spectrum, confirming our previous report of detection of CN emission in the 17 February 1985 MMT data¹.

All the MMT spectra listed in Table 1 have been ratioed and differenced both with the solar spectrum² and with that of a solar analogue to search for weak cometary emission features. Comparison of the February and March spectra of comet P/Halley indicates that the emission feature at 3,883 Å is the only feature present above the 1.5σ detection level in both spectra at the same wavelength and with a width larger than one resolution element. No statistically significant detection of the CN band was found in the November 1984 spectrum. Only a marginal detection of CN emission was indicated in the April spectrum, which may be explained by the fact that the comet was observed through a considerable air mass and for a shorter integration time than in February and March. No other cometary emission features would be expected to be detectable.

Fig. 1 Detection of the $\Delta v = 0$ band sequence of the violet CN system ($B^2\Sigma^+ - X^2\Sigma^+$) is illustrated in this averaged (February and March data) pre-perihelion MMT spectrum of P/Halley (1982i) which has been ratioed with the solar spectrum. The CN emission demonstrates the presence of a significant gas coma in the comet. This spectrum was binned in 10-Å intervals before division by the solar spectrum, which was also binned in 10-Å intervals. Note the colour difference, $\Delta(B - V) \sim +0.2$, in the sense (P/Halley-Sun) indicated by the slope of the ratioed continua.

Table 1 shows measurements and 2σ upper limits for the CN emission band fluxes obtained from the (Halley-Sun) difference spectra after normalization at the continuum near 3,883 Å. The CN band fluxes were converted to column densities, and CN production rates were calculated using the vectorial model³. In the calculation, photo-dissociation lifetimes ($r = 1$ AU) of 22,000 and 100,000 s were adopted for the CN parent and for CN, respectively. The assumed parent velocity was 0.8 km s⁻¹ and that for CN 3.0 km s⁻¹. Assuming $Q(\text{OH})/Q(\text{CN}) \sim 500$, the production rate of H₂O in P/Halley at $r \sim 4.7$ AU is estimated to be $Q(\text{H}_2\text{O}) \sim 2 \times 10^{27}$ molecules s⁻¹.

Photometric data derived from the continua of the MMT spectra, together with published broad-band photometry of comet P/Halley, provide evidence for the onset of sublimation of the nucleus. To our knowledge this represents the first observation of the onset of sublimation in any comet. The V magnitudes, uncorrected for aperture effects and derived by convolving the MMT spectra with the standard V passband transmission function⁴, are listed in Table 1. The comet was visible on the MMT television monitor during the February, March and April observations. In March and April the average seeing diameter was $\sim 1-2$ arc s and the images of P/Halley had soft appearances relative to stars in the same field, indicative of a resolved cometary image (angular diameter > 2 arc s). During these observations the comet was not seen on the television monitor more extended than 5 arc s to a surface brightness level of $V \sim 21-22$ mag arc s⁻². The spectrum in November was obtained using a blind offset, as the comet was too faint to be seen on the television monitor.

Table 1 MMT Reticon observations of P/Halley (1982i)

Date (UT)	r (AU)	Δ (AU)	Φ °	Aperture* (km)	$V^\dagger$ (mag)	$V(1,0)$ (mag)	$F(\text{CN})$ (erg cm ⁻² s ⁻¹)	$Q(\text{CN})$ (molecules s ⁻¹)
26.4 November 1984	5.60	4.76	5.6°	8,850	20.9	13.6	$< 1 \times 10^{-15}$	$< 6 \times 10^{25}$
17.2 February 1985	4.84	4.45	11.2°	8,050	19.9	12.8	$(3 \pm 2) \times 10^{-16}$	$(3 \pm 2) \times 10^{24}$
24.2 March 1985	4.50	4.73	12.1°	8,600	19.4	12.4	$(5 \pm 4) \times 10^{-16}$	$(4 \pm 3) \times 10^{24}$
18.2 April 1985	4.25	4.87	10.0°	8,850	18.7	11.8	$< 2 \times 10^{-15}$	$< 1 \times 10^{25}$

* Projected circle equivalent radius of 2×3 arc s aperture in November; projected radius of 5 arc s diameter circular aperture in February, March and April.

† Estimated internal error is ± 0.3 mag. Both magnitude and flux measurements for February data supercede those given in a preliminary report¹.

Fig. 2 Evidence for the onset of sublimation of the nucleus of comet P/Halley near $r \sim 6$ AU. $V(1,0)$ is the V magnitude of the comet reduced to a distance 1 AU from the Earth, 1 AU from the Sun and to a direction directly opposite the Sun. An inactive comet nucleus would have a constant $V(1,0)$ magnitude. Dates at the top represent mid-year epochs.

To remove brightness variations resulting from changes in the heliocentric and geocentric distances of the comet, the V magnitudes were converted to reduced magnitudes using

$$V(1,0) = V - 5 \log r - 5 \log \Delta - 0.039 \Phi \quad (1)$$

where $V(1,0)$ is the magnitude of the comet at $r = \Delta = 1$ AU, V is the observed magnitude (Table 1), Φ is the solar phase angle, and an asteroid phase function, 0.039, is assumed. In Fig. 2 the reduced magnitudes of P/Halley are plotted against the heliocentric distance; photometry published elsewhere³⁻¹¹ has also been included. An inactive cometary nucleus would be expected to have a constant $V(1,0)$ (except for the effects of rotation and aspect).

There is clear evidence for an increase in the brightness of the comet at $r \sim 6$ AU, indicative of the development of a dust coma (see Fig. 2). Significant continuous sublimation of the nucleus of P/Halley commenced sometime between mid-1984 and early 1985 (Fig. 2). This onset epoch is consistent with the observation of an extended coma reported in late September 1984 by Djorgovski and Spinrad¹². In fact the September appearance of the extended coma associated with comet P/Halley could have resulted from a rupture of a surface dust mantle because of solar heating after the 75-yr incubation period of the comet. Note that the lack of CN in the November spectrum (Table 1) does not preclude the estimated sublimation onset epoch, as CN emission would have been undetectable (at the 1.5σ level) with the MMT Reticon spectrograph even if the November band strength had been comparable with that observed in February 1985.

The constancy of the mean value of the reduced magnitude for $r > 8$ AU indicates that systematic sublimation was not occurring in comet P/Halley from $r \sim 12$ to 8 AU. Hence, we conclude that the observations obtained when the comet was located at $r > 8$ AU represent the inert nucleus. For $r > 8$ AU we calculate the mean reduced nuclear magnitude of the comet, $\overline{V(1,0)}$, to be 13.9 ± 0.5 mag, where the error represents the r.m.s. deviation in the data. The intersection of the sublimation curve with the $\overline{V(1,0)} = 13.9$ line in Fig. 2 gives a heliocentric distance corresponding to the onset epoch, $r \sim 6 \pm 1$ AU.

The photometric observations of comet P/Halley are plotted as a function of heliocentric distance in Fig. 3. The secular variation of the nuclear magnitude of comet P/Halley with heliocentric distance can be explained adequately by changes in heliocentric and geocentric distances and phase angle [equation (1)] during the interval 1982-85 ($r = 12-6$ AU). A

Fig. 3 Light curve of comet P/Halley (1982-85) showing the predicted nuclear magnitude (equation 2; dotted line) and the predicted total magnitude ($V \sim r^{-7 \pm 3}$; dashed line). The secular increase in brightness of comet P/Halley can be explained within the observational uncertainties by relative changes in distance (and phase angle) between the Earth, Sun and comet until the comet reached a heliocentric distance of $r \sim 6$ AU, when systematic brightening indicative of the dust coma development.

curve fitted to the photometric observations after the onset of sublimation indicates an initial dependence of the sublimation rate $V \sim r^{-7 \pm 3}$.

Figures 2 and 3 show that the photometric data obtained from comet P/Halley before $r \sim 8$ AU probably refer to the bare nucleus. Hence, an effective radius can be calculated using the mean reduced magnitude, from

$$p_v R^2 = k 10^{(0.4[V(\odot) - \overline{V(1,0)}])} \quad (2)$$

where $k = (1.5 \times 10^8 \text{ km})^2 / \pi$, p_v is the geometric albedo ($\lambda \sim 5,500 \text{ \AA}$), R is the effective (circle equivalent) radius of the nucleus, $V(\odot)$ is the apparent visual magnitude of the Sun (-26.7) and $\overline{V(1,0)}$ is the mean reduced magnitude of the comet nucleus, 13.9, derived above. We find for comet P/Halley

$$p_v R^2 = 0.5 \pm 0.2 \text{ km}^2 \quad (3)$$

which differ slightly from a previous determination by Hughes¹³.

As the albedo of the comet nucleus is not yet known, we adopt a plausible range of albedos, $p_v = 0.03-0.6$, which spans low-albedo asteroids to the higher-albedo icy surfaces such as the jovian satellites. For this albedo range, we calculate an effective radius for the nucleus of comet P/Halley, $R = 1-4 \text{ km}$. Note that if there is a significant contribution to the $\overline{V(1,0)}$ magnitude from a particulate halo surrounding the nucleus, then this range represents an upper limit to the effective radius of the solid-body nucleus of comet P/Halley.

The assistance of C. Heller at the telescope was essential for obtaining the observations reported here. We also thank C. Foltz and other members of the staff of the MMT Observatory for assistance. The MMT is operated jointly by the Smithsonian Institution and the University of Arizona. This research is supported by NASA grant NAGW-547 to Arizona State University.

Interplanetary conditions during 3-kHz radio-wave detections in the outer heliosphere

L. J. Lanzerotti & C. G. MacLennan

AT&T Bell Laboratories, Murray Hill, New Jersey 07974, USA

R. E. Gold

Johns Hopkins University Applied Physics Laboratory, Laurel, Maryland 20707, USA

A very important observation¹ regarding the plasma physics of the outer heliosphere has been that plasma-wave instruments on both the Voyager 1 and 2 spacecraft beyond ~12 AU detected, during the same interval of time, plasma waves (frequency ~3 kHz) that could possibly be associated with the turbulence expected at the heliopause. It was suggested that this turbulence had propagated inwards to the spacecraft, which would place the heliosphere boundary at ~46 AU. To interpret these unusual observations, it is important to understand the characteristics of the interplanetary medium at large heliocentric distances. We draw attention here to the low-energy charged-particle environment in the outer heliosphere during the observations of the unusual plasma-wave signals. These particle data suggest that the outer heliosphere was unusually stable and free of transient shock and particle events for the ~8 months during the wave observations.

Figure 1 shows the counting rates as a function of time for protons (~3–17 MeV) measured by the Low Energy Charged Particle (LECP) experiment² on both Voyager spacecraft from 1982 to 1984. The plotted data are 3-day averages. The dotted line on Fig. 1 is day 243, 1983, when the unusual plasma waves were first observed¹. The wave signals are reported to have disappeared in early spring 1984 (ref. 3). During this interval of 1983–84 (which we subsequently refer to as the signal period, SP) the two Voyager spacecraft were at approximately the same helio-longitude, with Voyager 1 increasing in helio-latitude from ~20.5° to ~22.5° and in distance from ~17.2 to ~19 AU while Voyager 2 remained approximately in the ecliptic plane, moving from ~12.5 to 13.7 AU (ref. 1) on its way towards encounter with Uranus in January 1986.

During the SP interval, Voyager 1 measured no energetic protons for about 200 days. Before day 243, 1983, and after about day 75, 1984, many transient proton enhancements were observed. Voyager 2, in the ecliptic plane, observed some proton activity at about day 270, but, in general, the activity in the SP interval was much suppressed compared with that before day

243, 1983, and after day 75, 1984. Examination of Voyager LECP ion data (~50 keV) shows that the only activity during the SP interval was from co-rotating interplanetary shocks⁴. This conclusion was also reached by the Voyager cosmic-ray instrument team studying >0.5-MeV protons⁵.

We suggest that this ~200-day interval of quiescence in the energetic ion population in the outer heliosphere was directly related to the fact that the anomalous plasma waves (waves at frequencies above the local plasma frequency in all cases) were observed. We suggest that the interplanetary medium at this time consisted only of outwardly propagating co-rotating shocks, providing a rather stable interplanetary environment for the propagation (and possibly generation) of plasma waves. No transient shocks from solar flares overtook the co-rotating shocks to disrupt the stability of the medium. Indeed, the medium may well have resembled, for ~200 days, the prediction of Burlaga⁶, who speculated that beyond ~10 AU the large-scale dynamics of the interplanetary medium could be dominated by pressure waves; the originating coronal signatures would be lost. The solar wind would, therefore, be more homogeneous on a large scale. We suggest that the dashed line in Fig. 1 marks the end of the wave observations in early spring³.

The basic question then arises as to the origins of the plasma waves detected during this interval by the two Voyager spacecraft. We note that in a stable medium consisting only of co-rotating shocks, the plasma waves, if generated at the plasma frequency at the heliosphere boundary, could propagate to the spacecraft in a medium undisturbed by disrupting transient events. The propagation could be across the shocks or along the spiral field configuration between the shocks. Further, the absence of energetic protons at both spacecraft for such a long interval implies the absence of such protons at the heliopause. Such energetic protons in association with transient shocks, in the turbulence of the heliopause, could disrupt the plasma-wave generation processes there. Alternatively, the observations of the unusual plasma waves during this time interval could arise from plasma-wave generation at about twice the local plasma frequency, at the co-rotating shocks, with the waves channelled preferentially between the shock structures in the unusually stable interplanetary conditions.

While considerable study and modelling have been reported on the large-scale magnetic character of the inner heliosphere^{7–10}, less work has been reported on the heliosphere structure beyond ~10 AU and, in particular, on the propagation of heliosphere plasma waves in the various magnetic structures formed by co-rotating shocks and/or by transient shock conditions. The possibility that the heliopause has been remotely detected during the stable interplanetary conditions reported here should stimulate work on studies of the propagation of plasma waves in the outer heliosphere in an ordered

Fig. 1 Proton counting rates (3-day averages) measured on the Voyager 1 (a; 3.4–17.6 MeV) and Voyager 2 (b; 3.0–17.3 MeV) spacecraft from 1982 to 1984. The dotted line marks the onset of 3-kHz radio-wave observations by Voyager¹. The dashed line marks the expected termination of the detection of the waves determined from considerations of the energetic ion fluxes in the outer heliosphere.

interplanetary environment devoid of transient shocks and energetic ions.

Characteristics of *in situ* coal gasification liquids from a cretaceous coal

Sujit K. Chakrabartty & Milan L. Selucky

Coal Research Department, Alberta Research Council,
Devon Coal Research Centre, PO Bag 1310, Devon, Alberta,
Canada T0C 1E0

The concept of harnessing energy from fossil fuel by gasification of coal in the ground has been revived with the aim to increase usable coal reserves and to minimize the environmental impacts of mining and other problems. We report here the characteristics of liquids formed as a by-product of an underground gasification pilot test burn of a Cretaceous coal seam at a central Alberta location. The simplicity of the composition of liquids produced suggests that *in situ* coal gasification may be an economically viable source of refinery feeds or fuel.

During the summer and early autumn of 1976, an exploratory field test of underground coal gasification was carried out in the Battle River coal field, ~195 km south-east of Edmonton, on a 3.6-m zone of Cretaceous sub-bituminous coal. This coal zone is part of the Horseshoe Canyon Formation and lies almost horizontally under ~18 m of fairly impervious shale and clay. A rectangular 18.3 × 9.1 m four-well system was placed in the direction of the face cleat to facilitate the breaking of the coal according to its natural trend. The boreholes were so linked by surface piping that any one hole could serve for air injection or for delivery of gas through a knock-out tank (for stripping tarry materials from the production gas) to the flare stack. During the gasification segment of the test burn, ~300 tonnes of coal were affected and 25,500 m³ of gas with a heating value of 3,700 kJ m⁻³ produced. Excavation of the site after the test burn indicated that 50 tonnes of dry coal were pyrolysed and gasified. A substantial quantity of tar and light oil was collected at the knock-out tank while the gasification was in progress. The simplicity of composition of these liquids suggests that by-products of *in situ* coal gasification may be an economically viable source of refinery feeds or fuel.

To provide laboratory support for the field test programme, we designed a simulator which used a 1 × 1 × 2 m coal block retaining most of the essential features of an undisturbed coal seam, and several simulations of underground coal gasification (UCG) were performed. Detailed descriptions of the simulation experiments¹ and field tests²⁻⁴ have been published elsewhere.

An insight into the composition of the organic content of the liquid effluents from the field tests was gained by liquid-liquid extraction of an aliquot of the product sample with an organic solvent, followed by IR spectrometry on the extract. The spectra, showing the presence of strong —OH and —O— bands, together with well-resolved 1,600–1,800 cm⁻¹ bands, were almost identical to spectra obtained for low-temperature pyrolysis tar of

Fig. 1 UCG liquids separation scheme.

low-rank coals. As the IR spectra of field and laboratory test samples indicated the presence of carboxylic acid and acid anhydrides, more detailed analyses of the liquid effluents collected as spot samples from the slipstream of the product line, from the knock-out tank and from the slipstream before the flare stack, were carried out as the field test progressed.

The final separation scheme (Fig. 1) was as follows: the samples were exhaustively extracted with chloroform; the solids were removed by filtration, and after removing chloroform from the filtered chloroform layer, a fraction of the residuum was separated into 'hydrocarbon' and 'resin' fractions by elution chromatography on a Florisil column. The resin fraction was steam-distilled and the steam-volatile fraction analysed for phenols by gas chromatography. The hydrocarbon fraction was separated on silica gel to give 'saturates' and 'aromatics', and each of these was re-separated by HPLC on amino phase (Lichrosorb-NH₂) using *n*-hexane eluent. HPLC separation showed that the 'saturates' from silica gel were contaminated with a small amount of 'aromatics' and these were removed as HPLC fraction 6. The HPLC 'saturates' fractions 4 and 5 were combined and further adducted with urea and thiourea to give urea-adduct, thiourea-adduct and thiourea-nonadduct following standard procedures⁵⁻⁷. Part of the 'saturates' was adducted on a molecular sieve (5 Å).

A large proportion of the steam-volatile fraction was identified as phenols (Table 1). The first member (phenol) of the homologous series was by far the most abundant constituent, followed by cresols (meta-, *m*-; para-, *p*-; and ortho-, *o*- in that order), while the remaining higher phenols were present only in minor proportion. The distribution of phenolic compounds remained constant during the steady burn period. A build-up of trimethyl phenols was noted in the product stream. Between 20 and 25% of total phenols escaping into the flare stack were identified as trimethylphenols on the fourth day of the burn period (sample F-4-3 and F-4-3₂).

The relative concentrations of the classes of compounds separated on the Florisil and silica column are shown in Table 2. The percentages of the chloroform-soluble liquids from effluents in steady burn conditions were 30% saturates, 25% aromatics, and 19% phenols; complex phenols plus compounds of high relative molecular mass (noted as non-volatile resin, Table 2) made up the last 26%. The error of analyses was ±3–5%. The hydrocarbons representing >50% of the UCG liquids were separated into saturates and aromatics on silica gel, and into six fractions

by HPLC. Preliminary characterization of the HPLC aromatic fractions came from a comparison with the retention times of a standard aromatic hydrocarbon mixture (benzene, naphthalene and phenanthrene); this suggested that fraction 1 consisted of mono- and di-aromatic hydrocarbons, fraction 6 mostly di-aromatic, and fraction 2 contained di- and tri-aromatic hydrocarbons only. More complex materials were present in fraction 3. Probable structures and compositions of all separated fractions were derived from subsequent analysis by gas chromatography and mass spectrometry (GC-MS).

The first major peak in fraction 1 was identified as naphthalene by GC-MS analysis. Subsequent peaks were methyl, dimethyl and trimethylnaphthalenes. Also, in the same chromatogram, a series of minor peaks can be observed between scan 2,000 and 3,000 belonging to acenaphthenes and possibly biphenyls. Fraction 2 seemed to be an intermediate zone between di- and poly-aromatics. Here the major group of compounds were dibenzofurans with minor amounts of acenaphthenes and biphenyls. The series of molecular ions M^+ 168, 182, and so on, represented dibenzofurans, while the isobaric acenaphthenes were concentrated in fraction 1. The higher members of the homologous series were the corresponding di- and trimethyl derivatives.

Fraction 3 was spectroscopically resolved into two groups. The first group was identified as anthracenes-phenanthrenes from the first member of the series to their tetramethyl homologues. No attempt was made to distinguish between anthracenes and phenanthrenes. The second group has the two largest peaks represented by pyrene and fluoranthene, together with smaller amounts of their monomethyl homologues. Careful extraction of mass spectral data for scan 3,500 and 4,000 indicated that a smaller amount of chrysene and a minute quantity of perylene were also present in this fraction. The total ion count

**Fig. 2** Mass chromatogram of saturate fractions.

(TIC) chromatograms provided an approximate distribution pattern, the relative order of abundance being anthracene-phenanthrene followed by pyrene-fluoranthene, di- and tetramethyl naphthalenes, methylnaphthalene, acenaphthene/biphenyl, dibenzofurans, chrysene and acenaphthenes.

Figure 2 is the TIC chromatogram of the combined saturate fractions 4 and 5. Here the peaks are equidistant; superimposed on them are two series of peaks—one at a lower scan and the other at a scan number from 4,100 to the end of the chromatogram. The identity of the group of major peaks was confirmed as a homologous series of *n*-paraffins. C_{14} – C_{24} paraffinic hydrocarbons were the main constituents. After the removal of paraffins on a molecular sieve, the sample was separated into urea and thiourea adducts and thiourea nonadduct (Fig. 3). The three fractions of adduction show, respectively, a wide distribution of very small amounts of open-chain to pentacyclic hydrocarbons. The presence of sterane and hopane hydrocarbons together with smaller amounts of tetra- and tricyclic hydrocarbons was identified from simple cross-scans of the thiourea nonadduct fraction combined with a consideration of the retention time. The retention times correspond to C_{21} – C_{29} steranes and C_{27} – C_{34} hopanes.

**Fig. 3** Mass chromatogram of urea and thiourea adducts and of thiourea nonadduct (number in upper right is total ion count).

Thus the composition and compound types present in the UCG liquid from a Cretaceous coal field were established. The paraffinic hydrocarbons, hopanes and steranes, along with aromatic hydrocarbons and phenols, represented >80% of all constituents. The abundance of the hydrocarbons was too high to discount them as coal seam contaminants; it is more likely that these are an integral part of the 'coal molecule' or are present in the coal as 'inclusion compounds'. Deno and co-workers⁹ obtained long-chain paraffinic acids by selective oxidation of various types of coals by trifluoroacetic acid oxidation. The simplicity of composition of the UCG liquids suggests the economic potential of this liquid for use as refinery feed or fuel.

A major omission of the evaluation of field tests and simulation experiments was the absence of quantification of liquid yield per tonne of coal. After excavating the test sites, it was observed that the gasification zones in the test burns always followed a pyrolysis zone containing disintegrated pyrolysed char retaining no trace of the cleat orientation. The temperature of this zone was below 600 °C as revealed by an analysis of the char⁴. It is then reasonable to assume that the UCG liquids were formed predominantly by pyrolytic reactions, and contained the most stable and steam-volatile components. An optimum estimate of liquid yield could thus be expected from the Fischer-Schrader assay of this coal. The 50 tonnes of dry coal (affected in the test burns) gave 15 tonnes of ASTM (American Standard for Testing Materials) volatiles which contained 5 tonnes of Fischer gas, 3 tonnes of product water and 7 tonnes of Fischer light oil and tar. The leftover carbon in the pyrolytic char was gasified to give 16 tonnes of carbon monoxide (~13,000 m³).

Steam-volatility of UCG liquids may cause contamination of the aquifer and create new ecological concerns. The close monitoring of groundwater around the Alberta test zone over a 2-yr period did not show any phenolic contamination to a detectable level in the groundwater. A continuous large-scale operation has to be monitored more thoroughly.

Synthetic seismogram modelling of the oceanic P_n phase

T. J. Sereno & J. A. Orcutt

Institute of Geophysics and Planetary Physics, Scripps Institution of Oceanography, La Jolla, California 92093, USA

The seismic oceanic P_n phase is characterized by low spatial attenuation, a high-frequency wavetrain of extremely long duration and an onset velocity near 8.0 km s⁻¹. In an effort to explain these properties, models have been proposed for the mode of propagation of this phase which include energy entrapment within a low-velocity channel^{1,2}, propagation within an extremely low-attenuation lithosphere waveguide^{3,4} and forward-scattering from local heterogeneity within the oceanic crust^{5,6}. Through synthetic seismogram modelling, we have generated realistic oceanic P_n phases for an oceanic lithosphere model that did not contain any of these intrinsic properties. The synthetic P_n phase can be explained rather simply as a set of refractions from the lower lithosphere with

Fig. 1 Complete synthetic seismograms at an epicentral range, R , of 1,000 km for a thrust fault source at 14.0 km depth. The fault had a dip of 45°, a rake of 270° and an azimuth relative to the receiver of 60°. *a*, Vertical component; *b*, horizontal component rotated 25° clockwise from the radial direction. Group velocities of 8.1, 4.7, 2.6 and 1.6 km s⁻¹ are indicated. Phase velocities between 3.85 and 25.0 km s⁻¹ were included in the calculation.

subsequent reverberations within the oceanic water column and sediment layer. Many of the spectral properties associated with layer reverberation observed in the synthetic P_n phase are revealed in data collected in the south-west Pacific. Complicated oceanic lithosphere models are not required to explain the gross characteristics of P_n propagation.

The realistic oceanic P_n phases were synthesized using wavenumber integration⁷. The technique involves a quadrature over wavenumber at fixed frequency points with the result then Fourier transformed into the time domain. The resulting seismograms contain all reverberations, including those off the free surface, as well as all P to S (primary to secondary) and S to P mode conversions. Although the algorithm is similar to the widely used reflectivity method⁸, it differs in several important respects. The inability of reflectivity to incorporate reverberations and mode conversions outside a 'reflection zone' that cannot contain the free surface renders the method inadequate for the study of P_n propagation. We will show that near-receiver sediment and water reverberations are quite important in the synthesis of oceanic P_n wavetrains and, therefore, that wavenumber integration is well suited for the study of this phase.

The most serious limitation of wavenumber integration is the restriction to models consisting of a stack of laterally homogeneous layers. We have chosen a model representative of normal oceanic lithosphere, consisting of a vertically inhomogeneous oceanic crust and upper mantle overlain by a 4-km-thick water layer and a 500-m-thick sediment layer⁹. The values of the quality factor, Q , chosen in agreement with seismic refraction studies¹⁰, were <500 for compressional waves in the crust and upper mantle and 50,000 in the oceanic water column. A low-velocity channel was not included and the seismic velocity was a monotonically increasing function of depth.

Figure 1 shows complete synthetic seismograms generated for a sub-Moho thrust fault at an epicentral range of 1,000 km. The vertical component is illustrated in Fig. 1*a* and the horizontal component in Fig. 1*b*. The division of these seismograms into two groups facilitates the schematic identification with the oceanic P_n and S_n phases. The group with an onset velocity near 4.7 km s⁻¹ (Fig. 1*b*) is grossly identified as the oceanic S_n phase. The first-arriving energy within this group is entirely comprised of horizontally polarized shear waves and is absent from the vertical component. The absence of a clear SV body wave at a velocity near the mantle shear velocity, 4.7 km s⁻¹, may indicate that the mantle shear Q used to calculate the synthetics, 225, was too low. Work is continuing in an effort to synthesize more realistic S_n phases.

The first-arriving group of energy in Fig. 1 has an onset velocity of 8.1 km s⁻¹, a duration of the order of 100 s and extends into

the onset of S_n . This group is characteristic of the oceanic P_n phase.

The importance of reverberations within the oceanic water column and sediment layer is most effectively demonstrated in the frequency domain. It is simple to show that the power spectrum of a wavelet reverberating in a single layer contains spectral peaks at frequencies given by

$$f_n = (2n+1) \frac{df}{2}, \quad (n=0, 1, 2, \dots) \quad (1)$$

where $df=1/T$ and T is the time between multiples. In the case of near-vertical incidence, T can be approximated by the two-way travel time in the layer and equation (1) represents the eigenfrequencies for an organ-pipe mode¹¹. The restriction of P_n to rays with turning points in the sub-Moho portion of the oceanic lithosphere requires phase velocities to be bracketed by the sub-Moho compressional velocity and that at the base of the lithosphere. In the case of the synthetics, this range is between 8.1654 and 8.2038 km s⁻¹. The resultant rays are quite steep at the receiver, justifying the use of the two-way travel time in equation (1). The $df/2$ offset of the spectral peaks is due to a π -phase shift between multiples¹². The width of the spectral peaks at frequencies given by equation (1) is governed predominantly by the impedance contrast at the boundaries of the layer. Thus the peaks associated with water reverberation, which actually occur between the free surface and the base of the sediments, are quite narrow. The sediment layer, on the other hand, acts as an extremely leaky waveguide for compressional waves because of the low impedance contrast at the ocean-sediment interface. This, coupled with the low value of Q in the sediments, results in broad spectral peaks for sediment reverberations. The power spectrum of a wavelet reverberating

Fig. 2 Power spectrum of the synthetic P_n wavetrain. *a*, Synthetic P_n wavetrain in Fig. 1a. *b*, First 3.0 Hz of the vertical-component power spectrum with vertical lines at frequencies associated with water reverberation. *c*, Horizontal component spectrum with vertical lines indicating predicted positions of spectral humps associated with S-wave sediment reverberation. The synthetics were limited to a Nyquist frequency of 6.4 Hz due to the high computational costs involved.

Fig. 3 Data collected in the south-west Pacific during the Ngendei Seismic Experiment. *a*, Hydrophone recording; *b*, the first 3.0 Hz of its corresponding power spectrum with vertical lines at predicted frequencies of water reverberation peaks. *c*, OBS vertical-component seismometer data and *d*, its corresponding power spectrum. Vertical lines indicate predicted positions of spectral humps associated with P-wave sediment reverberation.

in the oceanic water column and sediment layer thus consists of widely spaced spectral 'humps' due to sediment reverberation superimposed on finely spaced spectral 'peaks' associated with water reverberation.

Figure 2 illustrates this behaviour in the synthetic P_n power spectrum. Figure 2a shows the synthetic P_n wavetrain of Fig. 1a. The horizontal component power spectrum in Fig. 2c shows vertical lines indicating predicted positions of spectral humps associated with S-wave sediment reverberation. Figure 2b is the first 3.0 Hz of the vertical-component spectrum with lines at the predicted frequencies of water reverberation peaks. Figure 2 thus clearly illustrates the presence of these reverberations in the synthetic P_n wavetrain.

Data were collected during the 1983 Ngendei Seismic Experiment by an ocean bottom seismometer (OBS) array in the south-west Pacific (23°49' S, 165°32' W), ~900 km east of the Tonga trench¹³. Each OBS contained one vertical and two horizontal seismometers and a hydrophone. Figure 3 shows an example of these data along with their corresponding power spectra.

A clear feature of the P_n phase in Fig. 3c, also seen in the synthetic P_n phase of Fig. 2a, is a predominance of low frequencies late in the wavetrain. Modelling the decay rate of the energy in the signal pictured in Fig. 3c as an exponential of the form $e^{-\gamma t}$ for three separate frequency bands, each two octaves wide,

resulted in values of $\gamma = -0.005$ between 0.5 and 2.0 Hz, $\gamma = 0.003$ between 2.0 and 8.0 Hz and $\gamma = 0.055$ between 8.0 and 32.0 Hz. This result is in direct contrast to models of forward-scattered coda⁶ which predict the fall-off rate to be a decreasing function of frequency. This feature can, however, be explained as the superposition of different modes of reverberation.

The hydrophone is a more narrow band instrument than the OBS vertical component seismometer and is better able to isolate the water reverberations and their corresponding spectral peaks as depicted in Fig. 3b. The vertical-component seismometer, on the other hand, can record the dominant frequency associated with sediment reverberation and clearly exhibits the corresponding spectral humps in Fig. 3d. The predicted frequencies of spectral peaks in both Fig. 3b, d were calculated using values of the sediment and water layer velocities and thicknesses obtained in an independent study¹⁴. When comparing the synthetic spectrum (Fig. 2c) with the data spectrum (Fig. 3d); it is important to realize that the synthetics were computed up to a Nyquist frequency of only 6.4 Hz whereas the data extend to 64 Hz. Thus the water reverberation peaks, which are separated by <0.2 Hz, when plotted on a scale extending to 64 Hz, appear rather incoherent as in Fig. 3d. To illustrate sediment reverberation in the synthetic spectra, we used a thick sediment layer to reduce the peak spacing. In the synthetics, the spacing between sediment reverberation humps is 1 1548 Hz, while in the data it is 11 43 Hz.

The amplitude of the synthetic P_n phase was within a factor of 2 or 3 of the data amplitudes and decayed as $\text{range}^{-1.3}$, slightly faster than pure geometrical spreading. An event located by the National Earthquake Information Service (NEIS) with a published magnitude of 5.8 and moment of 2.6×10^{24} dyn cm was recorded by three of the OBSs at the Ngendei site. The event was a thrust fault source with an azimuth relative to the receiver of 90° at an approximate epicentral range of 920 km. The absolute amplitudes in the first 20 s recorded for this event ranged from 0.76 to 1.44 V. To obtain the maximum amplitude of the synthetic P_n phase, we used a thrust fault source with an azimuth relative to the receiver of 90° at an epicentral range of 900 km. The moment determined by NEIS was used and, after convolving with the instrument response, the resulting maximum amplitude was 0.420 V. Differences of this order can be easily explained in terms of differences in model parameters, fault orientation and focal depth.

The steep incidence of the rays within the oceanic water column and sediment layer implies that only very local changes in bottom topography can affect the propagation of P_n between a particular source and receiver. As long as the OBS is situated in locally smooth topography, the spectral characteristics of P_n mentioned above will be apparent. The main effect of an irregular bottom topography would be to reduce coherence between OBSs at different sites. If the sites are sufficiently separated as to allow changes in either water or sediment thickness and/or velocity, the resulting P_n coda would suffer a severe reduction in spatial coherence.

The oceanic P_n phase can be explained simply as a set of refractions from the lower lithosphere with subsequent water and sediment reverberations. Synthetic P_n wavetrains with durations of the order of 100 s were generated in the absence of scattering. Thus the propagation of the oceanic P_n phase does not require features of the oceanic lithosphere such as low-velocity channels, anomalously high Q values or thin high-velocity lenses, but rather can be explained in terms of simple models with monotonically increasing velocity-depth profiles containing no lateral heterogeneity.

The data used for this study were collected and analysed with the support of DARPA grant AFOSR-84-0043 and the synthetics calculations were supported by ONR contract N00014-80-C-0440.

Stopping of earthquake ruptures at dilational fault jogs

Richard H. Sibson

Department of Geological Sciences, University of California, Santa Barbara, California 93106, USA

Palaeoseismic studies over the past several years have indicated that segments of certain major faults tend to rupture at fairly regular intervals in characteristic earthquakes of about the same size¹. This implies the presence of local structural controls which govern the nucleation and stopping of ruptures. Understanding rupture arrest is important, not only because it governs the size of characteristic earthquakes, but also because deceleration of ruptures results in the radiation of high-frequency energy leading to strong ground motion². I show here that rapid opening of linking extensional fracture systems to allow passage of earthquake ruptures through dilational fault jogs in fluid-saturated crusts is opposed by transient suctional forces induced near the rupture tips³. Rupture arrest may then be followed by delayed slip transfer as fluid pressures re-equilibrate by diffusion.

Mapping of rupture traces within major strike-slip systems has shown that they are generally discontinuous on a range of scales^{4,5}. In the San Andreas system, echelon segmentation of the fault trace is common, with the trace stepping abruptly from one side to another of fault zones up to ~ 2 km wide. High-resolution microearthquake studies have demonstrated that large irregularities observed in the surface fault trace often extend throughout the seismogenic zone to depths of 10 km or more⁶⁻⁸. The mechanical implications of echelon fault segmentation have recently been examined in a two-dimensional static stress analysis⁹. Two important cases are considered (Fig. 1); for ease of reference, irrespective of shear sense or faulting mode, they are designated dilational and anti-dilational jogs, depending on the tendency for areal increase or reduction respectively through the step region. For an anti-dilational jog (for example, left step under right-lateral shear), the elastic interaction between echelon fault segments increases both the mean compressive stress between the segments and the frictional resistance at the segment tips, inhibiting slip transfer across the

Fig. 1 Likely development of extension fractures in association with dilational and anti-dilational jogs along a segmented fault, shown in relation to far-field principal compressive stresses, $\sigma_1 > \sigma_2 > \sigma_3$ (after ref. 9).

Fig. 2 Seismotectonic sketches illustrating the geometry of strike-slip earthquake ruptures within the San Andreas Fault system (stars, epicentre, arrows, propagation direction and extent of main-shock rupture; broad lines, surface breaks, dash-dot lines, micro-earthquake lineaments, stippling, rhomboidal areas of intense aftershock activity).

discontinuity. Such 'pinned' discontinuities form potential nucleation sites for moderate to large earthquakes^{7,9}. In contrast, for a dilational jog (for example, right step under right-lateral shear), frictional resistance at the segment tips is diminished, facilitating sliding, while mean compressive stress decreases throughout the inter-segment region, favouring the development of a linking fracture system involving extension and/or shear.

Thus, on the basis of this static analysis, echelon fault segmentation involving dilational jogs should present no major hindrance to the transfer of slip along fault systems⁹. Paradoxically, however, several recent strike-slip earthquake ruptures have terminated in the vicinity of dilational jogs which appear to have acted as kinetic barriers opposing rupture propagation. Seismotectonic sketches illustrating the rupture geometry in each case are given in Fig. 2.

The 1966 Parkfield earthquake (of M_L 5.5) is of particular interest as the latest in a series of characteristic $M_L \sim 5.5$ events that have previously ruptured the same Parkfield-Cholame segment of the San Andreas fault in 1934, 1922, 1901, 1881 and also possibly in 1857 as an immediate foreshock to the $M \sim 8$ event which ruptured through the 'Big Bend'^{10,11}. Waveform similarities suggest that the last three events, at least, share essentially the same rupture characteristics, with the implication of strong controls on the nucleation and stopping of these characteristic events. Final ground breakage associated with the 1966 event extended for ~ 35 km (ref. 12). Structurally significant features along the trace include a slight restraining bend (equivalent to an anti-dilational jog) associated with the epicentre, and a pronounced ~ 1 -km dilational jog between echelon segments across the Cholame Valley. While dextral strike-slip at the surface eventually reached ~ 0.2 m near the centre of the rupture, most, if not all of it developed by afterslip over a period of 2 months following the main shock¹³. On the basis of seismic strong motion data and the aftershock distribution, it has been argued that the main co-seismic rupture was vertical, extended from 3 to 8 km depth and propagated unilaterally southeastwards for ~ 25 km from the epicentral bend, with a mean slip of 0.6 m, to terminate in the vicinity of the right-step¹⁴. The surface fault break was discontinuous across the jog, but aftershock activity was particularly intense beneath a 3.5×1 km rhomboidal area immediately north-west of its inferred position, indicating that the echelon segmentation persisted throughout the seismogenic regime to a depth of around 12 km (ref. 6). There are indications of relative subsidence within this rhombic area over a period of weeks following the earthquake¹². The 8-km fault break extending south-east of the jog was probably

Fig. 3 Dilational jogs in various host rocks on a range of scales from natural fault systems (all drawn for dextral-shear sense). Black areas represent infillings of hydrothermal minerals or cemented breccias (a, quartz-chlorite fibrous infilling in metagreywacke²⁴; b, calcite infilling in flysch²⁵; c, quartz-epidote infilling in granodiorite²⁰; d, quartz infilling in granodiorite⁹; e, gold-quartz vein in greenstones²³; f, multiply quartz cemented breccia-vein in andesitic volcanics²²).

entirely the product of post-mainshock afterslip which decreased logarithmically with time along with the aftershock activity¹³.

Information on the 1979 Coyote Lake earthquake (M_L 5.9) on the Calaveras Fault is based largely on high-precision aftershock studies and waveform analyses, because no clear surface break was observed. However, the seismological data indicate behaviour similar to the Parkfield event, with the main rupture propagating unilaterally southeastwards to terminate adjacent to a dilational jog delineated by intense aftershock activity. Mainshock slip averaging ~ 0.2 m was largely confined to a subvertical rupture extending from 3 to 10 km depth, which propagated southeastwards from the focus for 6–14 km (refs 15, 16). Some 5 h after the main earthquake, beginning with an M_L 4.0 event, aftershock activity extended ~ 2 km south-west to an echelon fault segment and migrated southeastwards over a period of days to define a subsidiary slip plane 8 km in length at depths between 3 and 7 km (ref. 8). Diffuse aftershock activity occurred within the overlap zone.

In the 1979 Imperial Valley earthquake (M_L 6.6), the rupture propagated unilaterally northwestwards for ~ 35 km with an average co-seismic slip of ~ 0.4 m, terminating at a larger-scale dilational jog defined by the down-thrown Mesquite Basin. Surface faulting occurred only on the northern three-quarters of the rupture along the Imperial fault, and also along the subsidiary Brawley fault. Detailed analysis of the main rupture on the Imperial fault¹⁷ shows that the amount of strike-slip, the slip rate and the rupture velocity diminish abruptly north of the intersection with the Brawley fault, but that the rupture continued on past a small restraining bend to stop finally where the strike of the Imperial fault veers northwards. In the first 8 h following the main shock, aftershocks were almost entirely concentrated beneath a 7×11 km rhomboidal area extending north from the main rupture termination¹⁸.

From their geomorphic expression, it seems clear that many of these dilational jogs are long-lived structures with substantial strike-slip motion transferred across them through some form of linking fracture system. Evidence on the nature of these fracture systems comes from several sources. Experimental work on brittle failure has demonstrated the strong tendency for cracks

Fig. 4 a, Mixed extensional-shear fracture mesh model linking echelon fault segments across a dilational jog. b, Schematic representation of a dextral rupture with fields of compression (+) and dilatation (-) at the rupture tip encountering a dilational jog consisting of a single linking extension fracture (not to scale).

under shear (fault segments) to propagate into and terminate in; or become linked by extension cracks aligned perpendicular to the least principal compressive stress¹⁹; the same seems to hold true within natural fault systems²⁰. The diffuse, high b -value swarm seismicity sometimes associated with large dilational jogs has been satisfactorily modelled as resulting from a fracture system incorporating short shears linked by vertical extension fractures into a honeycomb mesh²¹ (see Fig. 4a). This is consistent with focal mechanisms obtained from aftershocks within the jogs which show a preponderance of strike-slip solutions with, rarely, some minor normal-slip^{6,8,21}. Smaller examples of dilational jogs, which have been described extensively on a range of scales from ancient fault zones^{9,20,22-25}, are also instructive. Echelon, planar fault segments tend to be linked through the jog regions by individual or multiple extension fractures, occasionally with subsidiary shears, or by the development of more extensive rhombic or lensoidal openings (Fig. 3). The linking fractures are commonly infilled by hydrothermal mineralization, forming extension veins, or contain breccias of wall-rock fragments cemented by hydrothermal minerals^{22,26,27}. Textural evidence often suggests a history of incremental opening for the extension veins, or of multi-episode brecciation and cementation^{22,26,28}. While they are clearly fault-related, the low clast/matrix ratios of these re-cemented breccias indicate significant dilation with included clasts of wall-rock remaining angular and showing little evidence for a derivation by frictional attrition²⁹. The important geometrical conclusion, however, is that the total extensional opening across the linking fracture system in the direction of fault movement is generally comparable to the slip on the echelon fault segments.

Assuming that the internal structure of the larger dilational jogs is analogous to that observed in these smaller-scale examples, we consider the problems associated with transferring co-seismic slip for moderate or larger earthquakes (>0.1 m, say) across such features if, as seems likely on comparative grounds, such slip transfer requires extensional opening of the same order within the jogs. Although the linking fracture system may resemble the mixed extensional-shear mesh model for

earthquake swarms²¹ (Fig. 4a), we represent it simply by an equivalent single extension fracture (Fig. 4b). While the deviatoric stress field within dilational jogs favours the opening of linking extension fractures⁹, static stress analysis does not consider problems associated with the rapid opening of such fractures in fluid-saturated crust. Throughout the seismogenic regime, fluid pressures may reasonably be assumed to be at least hydrostatic²⁸, increasing with depth at ≥ 100 bars km^{-1} . Unless the extensional opening takes place sufficiently slowly for the internal fluid pressures within the linking fractures (P_f) to remain the same as those in the wall-rock (P_w), the opening will be opposed by an induced suctional force (F_s) in the shear direction,

$$F_s = \Delta P w v \quad (1)$$

where ΔP is the average fluid pressure differential, ($P_w - P_f$), v is the vertical extent of the rupture and w is the width of the dilational jog (Fig. 4). Clearly, the magnitude of the induced pressure differential will depend on the porosity and fluid diffusivity of the surrounding rock mass. Fluids could enter the dilating fracture system either by channel flow along the fault segments or from wall-rocks adjacent to the fractures. The former can be neglected given the width of the jogs and the 1-10-s slip durations characteristic of moderate to large ruptures³⁰. At any depth within the seismogenic regime (approximately the top 10 km of crust for geothermal gradients of 25°C km^{-1}), the incompressibility of water is sufficiently high for a fluid volume increase $\leq 10\%$ to lower the fluid pressure to a negligible fraction of initial hydrostatic values³¹. For an infinite planar extension fracture opening an amount, δu , in a time, t , we can define an effective diffusive volume extending a distance, $L = (ht)^{1/2}$, each side of the fracture, where h is the fluid diffusivity of the wall-rock. If the wall-rock has a porosity, p , it follows that the conditions for creation of large fluid pressure differentials is

$$\delta u > 0.2 p L = 0.2 p (ht)^{1/2} \quad (2)$$

Taking a reasonable porosity of 5%, the 1-10-s range of earthquake slip durations, and estimates of fluid diffusivity in fault zones which range from $\sim 10^{-8} \text{ m}^2 \text{ s}^{-1}$ for impermeable clay gouge³² to bulk values³ of $1 \text{ m}^2 \text{ s}^{-1}$, δu must have minimum and maximum values of $1 \mu\text{m}$ and 30 mm , respectively, for large fluid pressure differences to develop. Because we are concerned with transferring slip >0.1 m across the jogs, an induced pressure differential approaching the initial hydrostatic value at any depth therefore seems likely, even if many extension fractures are involved in the linking system. With the tensile strength of rocks rarely exceeding 100 bar, it is easy to see how the high-dilation breccias described above may form by hydraulic implosion of the wall-rocks into extending fractures as a result of these transitory fluid pressure differences (Fig. 4) (see refs 27, 29). For a dilational jog extending to a depth of 10 km, the average pressure differential $\Delta P \approx 500$ bar and from equation (1), F_s scales with the width of the jog for ruptures occupying the entire seismogenic zone. The work done in opening linking extensional fractures against the resistive suctional force is

$$W_s = \delta u F_s = \delta u w v \Delta P \quad (3)$$

For appropriate values, $v = 10 \text{ km}$, $w = 1 \text{ km}$ and $\delta u = 0.1 \text{ m}$, $W_s = 5 \times 10^{13} \text{ J}$. From the Gutenberg-Richter relationship³³, this is comparable to the wave energy released by an earthquake of surface wave magnitude $M_s 6$ (similar to those under discussion), giving some idea of the extent to which the opening of extension fractures within a dilational jog may drain energy from a propagating rupture tip.

The difficulties in transferring earthquake slip across the larger jogs are thus apparent. Rapid opening of extension fractures is strongly opposed by induced fluid pressure differentials, while such drops in fluid pressure as occur within the jog cause dilatancy hardening, increasing effective normal stress and shear resistance on subsidiary shears. The stopping mechanism also provides an explanation for the observed time dependence of

slip transfer and aftershock migration across dilational jogs. Strain-energy concentrations around the end of the arrested rupture may be slowly dissipated by slip transfer across the jog as fluid pressures re-equilibrate by diffusion to allow the necessary extensional opening within the linking fracture system. Similar control of aftershock activity by fluid diffusion has been suggested before³⁴, but not at such specific structural sites. The range of possible fluid diffusivities, noted previously, is sufficiently large for the rate of slip transfer to vary considerably, as is observed. Time-dependent displacement and fluid transfer around the dilational jog at Parkfield should clearly be closely monitored following the next characteristic M_L 5.5 event, which is expected in 1988 ± 4 yr (ref. 10).

Strontium content of ostracods indicates lacustrine palaeosalinity

Allan R. Chivas*, Patrick De Deckker†
& J. Michael G. Shelley*

* Research School of Earth Sciences and † Research School of Pacific Studies, Australian National University, GPO Box 4, Canberra, ACT 2601, Australia

Individual non-marine ostracod valves contain Sr in proportion to the Sr content of their host lake water. Two commonly coexisting, large planktonic species, *Mytilocypris praenuncia* and *Australocypris robusta*, have a Sr distribution coefficient K_D (Sr/Ca) of 0.082 which is independent of temperature in the range 10–18 °C. If the relationship between salinity and the Sr content of a hydrologically simple lake is known, palaeosalinities can be calculated from fossil ostracods. We present here palaeosalinities for the past 10,000 yr for Lake Keilambete, Victoria, calculated from ostracod Sr/Ca of fossil material which are in striking agreement with independent interpretations of palaeosalinity. The range of salinity spans 14–95‰. We also show that a reliable quantitative continuous indicator of lacustrine palaeosalinity is important for the elucidation of continental palaeoenvironments for palaeoclimatology and archaeology and ocean-continent climatic correlations and interactions.

The rapid advance in the knowledge of Quaternary global climate, stemming largely from the study of Foraminifera from

the ocean basins¹⁻³, has not been matched by equivalent progress in continental environments. Lacustrine sediments can supply information on changing continental climate. Those techniques commonly applied to lacustrine sediments, including sedimentary facies analysis, palynology, documentation of biota (such as ostracods and diatoms) with diagnostic salinity or temperature tolerances produce useful limiting ranges of palaeoenvironmental conditions. Oxygen-isotope studies of authigenic or biogenic lacustrine precipitates are commonly hampered by unknown previous $\delta^{18}\text{O}$ water compositions, which may have varied as a function of salinity (precipitation/evaporation ratio), precipitation regime and temperature and varying contributions from multiple fluvial and/or groundwater sources. What is lacking is a method capable of eliciting continuous salinity or temperature variations from lacustrine sediment cores.

Ostracods are considered to be ideal monitors of water quality because, before reaching maturity, they rapidly shed their shells several times (up to nine times, at approximately weekly intervals) during growth and the source material for their shells comes entirely from the host water⁴. We have shown previously⁵ that the Mg content of some non-marine ostracod shells is a function of salinity and temperature and that coupled Mg/Ca and $\delta^{18}\text{O}$ measurements might provide a record of combined palaeotemperature and palaeosalinity. However, the Sr/Ca ratios of the calcitic carapaces of the ostracod *Mytilocypris henricae*, grown in controlled conditions in aquaria and from natural lakes⁶, appear essentially independent of temperature (T) in the range 10.5–25 °C. Specimens of *A. robusta*, which is a species phylogenetically related to and of similar shape and size to *M. henricae*, collected at different seasons ($T = 10.2$ –18 °C) from Lake Keilambete in western Victoria (lat. 38°12' S; long. 142°53' E), share the same chemical relationship (Table 1). This raises the possibility that the Sr content of some non-marine ostracods may be used to determine palaeosalinity through the former Sr contents of the water.

A reconnaissance study of Sr/Ca ratios of carapaces from live ostracods from a series of south-east Australian lake waters⁵ of salinity 1.3–73‰ suggested that the Sr content of the shell was a direct and positive function of the Sr content of the lake water. We examined the Sr/Ca ratios of shells of 18 species, namely, *Australocypris* (two species), *Mytilocypris* (five species), *Diacypis* (three species), *Reticypis*, *Cyprinotus*, *Limnocythere* (three species), *Ilyocypris*, *Cypricercus* and *Cypretta*. We conclude that the distribution coefficient, K_D (Sr/Ca) = $[\text{Sr/Ca}]_{\text{CaCO}_3}/[\text{Sr/Ca}]_{\text{H}_2\text{O}}$, may be species dependent, although to a smaller degree than is the K_D (Mg/Ca) (ref. 5). The larger genera *Mytilocypris* and *Australocypris* have identical K_D (Sr/Ca). For modern *A. robusta* from Lake Keilambete (Table 1), K_D (Sr/Ca) ~ 0.082 .

For the first application of the Sr/Ca palaeosalinometer, we examined fossil ostracods from a lake which has simple hydrological characteristics. Lake Keilambete is a near-circular maar lake^{7,8} (area of lake 2.7 km²; area of catchment, that is, to crater rim = 4.2 km²) with input received only by direct precipitation, and water loss only by evaporation⁷. Thus, lake levels and the concentration of dissolved salts reflect changes in precipitation/evaporation, and documentation of sedimentary facies variations⁸ and palynology⁹, and identification of diagnostic ostracod species¹⁰ from cores spanning the past 10,000 yr have been used previously to infer changes in climate. The chronology of core KN (Fig. 1), representing 10,000 yr of sedimentation in 415 cm, is well controlled by 18 ¹⁴C dates^{7,9,11} that have been correlated from adjacent cores by comparison with a distinctive sequence of white aragonite and calcite microlaminar.

The Sr/Ca analyses of individual ostracods are presented in Fig. 1a. The $[\text{Sr/Ca}]_{\text{CaCO}_3}$ has been expressed as palaeosalinity using K_D (Sr/Ca) ~ 0.082 and the 1983 lake composition (mean salinity 73‰, and mean $(\text{Sr/Ca})_{\text{CaCO}_3}$ of 0.00635). This assumes that values for both salinity and Sr content are conservative and that the Ca content of the water is unimportant. *M. praenuncia* is generally present from 0 to 290 cm; ostracods are scarce in the interval 290–350 cm; and from 350 to 415 cm *A. robusta* is

Fig. 1 *a*, Palaeosalinity curve for Lake Keilambete based on Sr/Ca composition (lower scale) for ostracods from 34 horizons within core KN. The data are principally from *Australocypris robusta* (●), *Mytilocypris praenuncia* (○), with some results for *Leptocythere lacustris* (×) and *Diacypris compacta* (+). Sr/Ca results for coexisting *M. praenuncia* and *D. compacta* at 110 and 120 cm suggest that *D. compacta* may incorporate more Sr ($K_D(\text{Sr/Ca}) \sim 0.10$) at the same conditions than does *M. praenuncia*. Between 20 and 90 cm, the dashed line records the Sr/Ca variations for *D. compacta* and *L. lacustris*. The parallel dotted line at lower salinity based on the species differences in $K_D(\text{Sr/Ca})$ may be a better indicator of salinity. Seventeen Sr/Ca values for modern *A. robusta* are incorporated in a histogram above zero depth. The horizontal dashed line at 175 cm indicates the first appearance of authigenic dolomite. *b*, Palaeosalinity curve (smoothed, based on 40 samples) derived from sediment grain-size analysis⁸. A calibration of the proportion of the >44-μm fraction of modern bottom muds as a function of present water depths (from 0 to 11 m) was applied to the proportion of the >44-μm fraction of samples from core K4.

present. At one horizon (100 cm) both species are recorded, and each has a similar Sr/Ca value. Analysis of up to five specimens from some levels show a tight cluster of Sr/Ca results. Between 20 and 90 cm, there is a paucity of *M. praenuncia* and we show the Sr/Ca results for *Leptocythere lacustris* and *Diacypris compacta*. We have insufficient information from modern lakes to establish $K_D(\text{Sr/Ca})$ for these species, but their analyses appear to fit within the trend described by analyses of the two principal species. The trend also compares favourably with Bowler's⁸ palaeosalinity curve interpreted from sedimentary grain-size analysis (Fig. 1*b*). We suggest that the $K_D(\text{Sr/Ca})$ for all these species may be similar.

There are several striking similarities between the palaeosalinity curves derived from $(\text{Sr/Ca})_{\text{ostracod}}$ and by grain-size analysis. The most saline water (at 2,600 yr BP, 100 cm) is estimated to have been ~100% by grain-size analysis and 90–95% by Sr/Ca. Similarly, the lowest salinity at 6,400 yr (260 cm) is estimated to have been 12 and 14% respectively. Both methods assume constancy of salts in the lake. One is based on fossil chemistry indicating past water chemistry, the other on texture of sediments to indicate past water levels, which in turn indicate palaeosalinity in a closed system. The close correspondence between the two independent sets of results is strong evidence for the correctness of the assumption. The significant difference in results from the two methods is that the Sr/Ca data suggest that a period of high salinity began earlier (at 4,200 yr, 175 cm) than that estimated by grain-size analysis. The interpretation based on Sr/Ca is logical, because at 175 cm and higher in the core, authigenic dolomite displaces authigenic aragonite. An abrupt increase in salinity (Mg content) at this point is likely. The previously documented salinity tolerances^{10,12} for *M. praenuncia* and *A. robusta* are 5–43% and 7–145%, respectively. Our data suggest that *M. praenuncia* existed at up to 95% salinity.

Further comment on the palaeoclimatic implications of the Lake Keilambete region would only repeat Bowler's work^{7,8}. We conclude that the Sr/Ca of non-marine ostracods faithfully records palaeosalinity. Those species that have large salinity tolerances (for example 3–150%) are exceedingly useful, and their Sr/Ca provides a potentially continuous palaeosalinometer, free of the discontinuities inherent in the estimation of palaeosalinity by recognition of biota with limited and specific salinity ranges. The reliability of this method will be governed by the hydrological setting of those lakes studied. Small tectonically stable closed basins seem suitable; volcanic and impact crater basins which have negligible groundwater

Salinity (*S*‰) equated to the total dissolved solutes by the formula of Williams¹⁴. Distribution coefficient, $K_D = [\text{Sr/Ca}]_{\text{CaCO}_3} / [\text{Sr/Ca}]_{\text{H}_2\text{O}}$. Chemical analyses^{5,6} were by very high-resolution inductively coupled argon plasma emission spectrometer (ICPAES). All concentrations were greater than an order of magnitude above the detection limits which are Ca^{2+} 0.02 p.p.b. (parts per 10⁹) and Sr^{2+} 0.03 p.p.b. in solution.

inflow or leakage are ideal. Because the varying $\delta^{18}\text{O}$ value of water during evaporation can be largely predicted as a function of salinity¹³, once palaeosalinity is determined from ostracod Sr/Ca, a semi-continuous record of calculated $\delta^{18}\text{O}$ of lake water might be coupled with ostracod Mg/Ca (ref. 5) or $\delta^{18}\text{O}$ of ostracod valves or other calcareous biota to indicate lacustrine palaeotemperatures.

At present, the interpretation of continental palaeoclimatic changes is largely restricted to consideration of changes in precipitation/evaporation (P/E), without indication of whether these variations are due to changes in precipitation (P), evaporation (E), or both. A resolution of quantitative continental palaeotemperature and lacustrine palaeosalinity would allow an independent estimation of past precipitation and temperature regimes.

We acknowledge assistance from Trevor Dowling, Dominique Thuriot and Cecily Vlastuin in the laboratory and Koen Martens and Brad McDonald in the field. We thank S. R. Taylor for allowing J.M.G.S. to use the high-resolution ICP spectrometer for Ca and Sr analyses; and Charles Barton for making available his Keilambete cores. This research was supported by the SLEADS (Salt Lakes, Evaporites and Aeolian Deposits) project of the Research Schools of Earth Sciences and Pacific Studies.

Adaptation of photosynthetic apparatus of marine ultraphytoplankton to natural light fields

A. Michelle Wood

Department of Biology, Whitman Laboratory, University of Chicago, Chicago, Illinois 60637, USA, and Bigelow Laboratory for Ocean Sciences, West Boothbay Harbor, Maine 04575, USA

The discovery of widely distributed populations of chroococcoid marine cyanobacteria (*Synechococcus* spp.) deep in the water column has focused attention on the autotrophic potential of small (<10 μm) size classes of marine phytoplankton^{1–5}. These organisms contain light-harvesting pigments which specifically absorb in the blue and green regions of the spectrum^{6–11}. Despite the fact that sea water acts as a monochromatic filter, allowing only the blue and blue-green wavelengths to penetrate¹², essentially all estimates of the photosynthetic rate of ultraphytoplankton at depth have ignored the changing spectral composition of the natural light field and simulated only the *in situ* light intensity^{4,5,13}. Here I show that the spectral composition of available light must be considered in estimates of water column productivity and that the depth of the euphotic zone varies between different ultraphytoplankton strains depending on the composition and organization of the photosynthetic apparatus.

Four experiments were performed, each modelled on the work of Jenkin¹⁴. In experiments 1–3, the photosynthetic performance of two phycoerythrin (PE)-containing *Synechococcus* clones was compared with that of PE-lacking *Synechococcus* clones at different light intensities in artificial white light (AWL) and at 15, 30,

45 and 60 m depths in the euphotic zone of clear ocean water (Table 1). In almost all cases, the cyanobacteria showed higher rates of photosynthesis in AWL than in natural light of comparable intensity, indicating that simulated *in situ* techniques probably overestimate the contribution of *Synechococcus* to primary productivity at depth. In AWL, the effect of decreasing light intensity was approximately equal for all the clones; the cellular rate of photosynthesis at 37 $\mu\text{E m}^{-2} \text{s}^{-1}$ was $\sim 20\%$ ($\pm 3\%$) of the rate at 260 $\mu\text{E m}^{-2} \text{s}^{-1}$. In contrast, the photosynthesis-irradiance relationships in natural light show marked differences between clones. In experiment 3, clone WH5701 showed no detectable ¹⁴C uptake at 60 m, although the two PE-containing clones, WH8018 and WH7803, showed photosynthesis rates of 6.78 and 8.42 fg C per cell per h, respectively. Thus, while the PE-lacking clone had reached its compensation light intensity, the rate of photosynthesis of clone WH8018 was decreased by only 70% compared with its rate at 15 m; the photosynthetic rate of clone WH7803 at 60 m was similarly decreased by only 67%. This pattern was repeated in all three experiments with the cyanobacteria; the photosynthetic rate at 60 m compared with that at 15 m was inhibited to the greatest extent in the PE-lacking clones, to a lesser extent in clone WH8018, and to the least extent in clone WH7803.

This rank order corresponds to the presence of accessory light-harvesting pigments which absorb light at wavelengths that penetrate to 60 m. The PE-lacking clones contain phycocyanin (PC) and allophycocyanin (APC) as their principal accessory pigments; these pigment proteins have absorption maxima at 620 and 650 nm, respectively¹⁵. Clone WH8018 contains PC and APC, but also contains a PE closely resembling C-phycoerythrin as the major light-harvesting pigment; this PE contains only phycoerythrobilin (PEB) chromophores (absorption maximum = 550 nm)^{7,16}. WH7803 also contains a PE as its major light-harvesting pigment; this PE, however, contains both PEB and phycobilin (PUB) chromophores. The PUB chromophore has an absorption maximum at 492 nm and its presence enhances light-harvesting ability at blue wavelengths¹⁶.

The wavelength (λ) of maximum absorption *in vivo* and the presence or absence of different phycobiliproteins in marine *Synechococcus* spp. are under genetic control and independent of cell nutrient status¹⁷. Thus, the rank order for *in situ* photosynthesis observed in the present study should also be observed in natural populations. The relative differences between clones are probably not as great as would be seen in nature, as the cultured cells were grown in the presence of excess nutrients and undoubtedly contain more total pigment per cell than would individuals growing *in situ*. Increased total absorbance associated with high cellular pigment concentration would partially compensate for poorer relative absorption of blue light by genotypes which lack PE or contain a PE composed of only PEB chromophores.

Phycobiliproteins are closely related and are thought to have arisen by duplication of a common ancestral gene sequence^{18–22}. On the basis of subunit structure^{9,21}, sequence homology^{18–22}, distribution among taxa²², serological affinity²² and *in vivo* organization^{15,23,24}, the phycocyanins and allophycocyanins are viewed, phylogenetically, as the older forms^{18–22}. Phycoerythrins, particularly those containing both PEB and PUB chromophores, evolved more recently^{18–22}. In the marine *Synechococcus*, it seems that natural selection has favoured this evolutionary progression since, as shown here, each molecular step which increases the complexity of the photosynthetic apparatus, also increases the depth at which net photosynthesis can be achieved.

The theory that photosynthetic marine organisms possess pigments which complement the spectral composition of available light is an old one^{25,26} which has been widely accepted despite contrary empirical evidence for a number of species^{27,28}. The data presented here support the theory and suggest that complementary chromatic adaptation is an evolutionary rather than a physiological process in marine *Synechococcus* spp. If this is the case, the PE-containing genotypes, particularly those

Table 1 Comparison of photosynthetic rates of different clones

Experiment	Environmental conditions	Total PAR ($\mu\text{E m}^{-2} \text{s}^{-1}$)	% Surface irradiance	Rate of photosynthesis (fg C per cell per h)

Values are means of duplicate samples; ND indicates no detectable ^{14}C incorporation; dashes indicate lost samples; AWL, artificial white light. Clonal isolates of the eukaryotic ultraphytoplankton *Thalassiosira oceanica* Hasle and Heimdal (clone 13-1) and *Pavlova* sp. (clone NEP), and marine *Synechococcus* spp. clones WH7803 and WH8018 (which contain PE), and WH5701 and WH8018 (which lack PE) were obtained from the Center for Culture of Marine Phytoplankton (Bigelow Laboratory for Ocean Sciences). Clones 13-1 and NEP were isolated by R. R. L. Guillard in 1958 from surface waters in the Sargasso Sea and Gulf Stream, respectively. Clone WH8007 was isolated in 1980 from surface waters on the continental shelf of the northeastern United States by L. Provasoli. Isolation data for the remaining clones are given elsewhere⁷. The average diameter of the *Synechococcus* clones is 1–2 μm ; that of clone NEP is 6 μm ; and that of clone 13-1 is 3 μm . All experimental work was carried out onboard the R/V *Cape Hatteras* between 29 September and 14 October 1983, at four stations in the eastern edge of the Gulf Stream, between 29° and 34° N. Expendable bathythermograph data showed that the upper 75 m of the Gulf Stream in this region was isothermal at between 27.6 and 28.1 °C. Cultures were maintained in dilute cell suspensions (absorbance, $A_{\lambda\text{max}} \approx 0.3\text{--}0.4$) at the early exponential phase of growth by repeated transfer into f/2-silica or f/2 media³⁶, and incubated at *in situ* temperatures (28 °C) with continuous illumination under Cool White fluorescent lights (General Electric) at an intensity of 50 $\mu\text{E m}^{-2} \text{s}^{-1}$. The cultures had been pre-acclimated to this light regime for 1 month (>10 generations) before the cruise. Before each experiment, the cultures were diluted into fresh sterile media as necessary to achieve approximately equal absorbance values ($A_{\lambda\text{max}} \approx 0.2$), subsampled for cell counts, and spiked with ^{14}C -labelled sodium bicarbonate. The cultures were then subdivided into clear, 50-ml polycarbonate centrifuge tubes (Nalgene), sealed with a cap which allowed compensation for changes in external pressure, and incubated either onboard ship at 28 °C under Cool White fluorescent lights or at different depths in the water column in holders suspended from the ship's hydrowire. The holders were of clear Plexiglass, with clips holding the tubes to a bottom panel. Water circulated freely above and around the tubes. In the shipboard incubator, light was attenuated by neutral-density white Plexiglass panels. At the end of the incubation period, the rate of ^{14}C incorporation into organic material was determined by acidification and bubbling⁷; rates were corrected for dark uptake. Each experiment began approximately 1 h before local apparent noon, and continued for no more than 3 h to minimize the effect of diurnal changes in the spectral composition of solar radiation incident on the sea surface. Skies were partly cloudy during expt 1, and for the first half hour of expt 4, but were clear during expts 2 and 3 and during the last 2½ h of expt 4. The intensity of photosynthetically active radiation (PAR) and attenuation of light at 440, 520, 550 and 670 nm were determined using a Li-Cor underwater quantum meter and a four-channel underwater photometer. At all stations, the optical properties of the water corresponded to Jerlov type I oceanic water¹², with the 1% light level between 90 and 110 m; per cent transmittance in the top 10 m for light at 440, 520, 550 and 670 nm averaged 82.5, 79.8, 63.1 and 3.3%, respectively.

containing a phycoerythrin composed of PEB and PUB chromophores, would be expected to dominate natural populations of *Synechococcus* in oligotrophic waters where the photic zone can exceed 100 m; this appears to be the case as PE-lacking strains have never been found among oceanic isolates (J. B. Waterbury, personal communication) and strains containing a phycoerythrin with PEB and PUB chromophores are much more common among oceanic isolates than strains containing a phycoerythrin with only PEB chromophores^{6,7}. Note also that there is evidence for parallel evolution in *Oscillatoria erythraea* (Trichodesmium), the only other abundant planktonic cyanobacterium in oligotrophic ocean waters; this species also has a PE composed of both PEB and PUB chromophores²⁹.

In experiment 4, the performance of *Synechococcus* clone WH7803 was compared with that of two eukaryotic species: *Thalassiosira oceanica* Hasle and Heimdal (clone 13-1) and *Pavlova* sp. (clone NEP). The results (Table 1) show that while *Synechococcus* spp. containing a phycoerythrin with both PEB and PUB chromophores may have a competitive advantage in deep water compared with other cyanobacteria, the eukaryotes have a greater ability to adapt to the changing spectral composition of light fields in the open ocean. All three clones showed an approximately equal photosynthesis-irradiance relationship in AWL (Table 1), but when the rate of cellular photosynthesis at 60 m was compared with that at 15 m, the *Synechococcus* clone showed the greatest inhibition (Table 1); this is because the

Fig. 1 *In vivo* excitation spectra for fluorescence emission by chlorophyll *a* at 680 nm in the marine *Synechococcus* (a, b) and eukaryotic ultraphytoplankton (c) clones used in the present study. Light energy absorbed by the Soret band of chlorophyll *a* is clearly transferred through the photosynthetic apparatus to a greater extent in the eukaryotes than in the cyanobacteria.

Methods. Cells from exponentially growing cultures were suspended on Whatman GF/B glass fibre filters and spectra obtained in ratio mode on a Baird Atomic SF-1 spectrofluorometer, with excitation and emission bandpass settings of 2 and 32 nm, respectively. Cells had been maintained at 24 °C under continuous illumination (Cool White fluorescent lights) at 50 $\mu\text{E m}^{-2} \text{s}^{-1}$.

Soret band of chlorophyll *a* can drive photosynthesis to a greater extent in the eukaryotes than the marine *Synechococcus* (Fig. 1). This significant difference in the organization of the photosynthetic apparatus of prokaryotic and eukaryotic ultraphytoplankton has not previously been reported and suggests strongly that eukaryotic ultraphytoplankton have the potential to out-compete marine *Synechococcus* at extreme depths where only blue and violet light penetrate, a conclusion which is independently supported by the work of H. W. Glover, M. Keller and R. R. L. Guillard (unpublished). In view of recent reports that small eukaryotic cells are occasionally more abundant than *Synechococcus* at depth³⁰⁻³⁵, eukaryotic ultraphytoplankton must be viewed as a potentially important source of new particulate material in deep ocean water.

I thank the captain and crew of the R/V *Cape Hatteras*, P. M. McGilivray, A. Messer and J. C. Haney for shipboard assistance; R. R. L. Guillard, R. H. Haselkorn, D. A. Phinney, R. W. Spinrad and L. M. Van Valen for useful discussion; and C. R. Boake, Q. Dortch, T. Price, J. B. Waterbury and C. S. Yentsch for critically reading the manuscript. This work was supported by NSF grant OCE-8110707 (to L. R. Pomeroy), by DOE contract DE-ACO2-81ER60014 (to A.M.W. and R. S. Lande), and by an American Association of University Women Postdoctoral Fellowship (to A.M.W.). This is Bigelow Laboratory contribution 85005.

Odorant-sensitive adenylate cyclase may mediate olfactory reception

Umberto Pace, Emanuel Hanski*, Yoram Salomon* & Doron Lancet

Department of Membrane Research and * Department of Hormone Research, Weizmann Institute of Science, Rehovot 76100, Israel

The mechanism of the sense of smell has long been a subject for theory and speculation¹⁻⁵. More recently, the notion of odorant recognition by stereospecific protein receptors has gained wide acceptance⁶⁻¹¹, but the receptor molecules remained elusive⁹⁻¹⁵. The recognition molecules are believed to be quite diverse^{9,11,13-15}, which would partly explain the unusual difficulties encountered in their isolation by conventional ligand-binding techniques^{12,13}. An alternative approach would be to probe the receptors through transducing components that may be common to all receptor types^{7-9,12-14}. Here we report the identification of one such transducing molecular component. This is an odorant-sensitive adenylate cyclase, present in very large concentrations in isolated dendritic membranes of olfactory sensory neurones. Odorant activation of the enzyme is ligand and tissue specific, and occurs only in the presence of GTP, suggesting the involvement of receptor(s) coupled to a guanine nucleotide binding protein (G-protein)¹⁵⁻¹⁹. The olfactory G-protein is independently identified by labelling with bacterial toxins, and found to be similar to stimulatory G-proteins in other systems¹⁷⁻¹⁹. Our results suggest a role for cyclic nucleotides in olfactory transduction^{13,20-22}, and point to a molecular analogy between olfaction and visual^{15,16}, hormone^{17,18} and neurotransmitter¹⁹ reception. Most importantly, the present findings reveal new ways to identify and isolate olfactory receptor proteins.

We have recently described a preparation of sensory cilia from frog olfactory neuroepithelium¹¹. These isolated extensions of the chemosensory dendritic membranes are believed to contain the olfactory receptive apparatus¹⁰⁻¹⁴, in much the same way as isolated retinal rod outer segments contain the molecular photoreceptive machinery^{15,16}. We found that the olfactory cilia preparation contains adenylate cyclase at nearly 15 times higher specific activity than membranes from brain or whole olfactory epithelium, both known as rich sources of the enzyme^{20,23} (Fig. 1a). From the change of specific activity after deciliation (Fig. 1a), we calculated that the cilia contain ~40% of the total epithelial adenylate cyclase, although they contain only ~3% of the total protein. Non-sensory cilia prepared from respiratory epithelium showed only 1% of the specific activity found in the olfactory organelles (Fig. 1a). GTP and its non-hydrolysable analogues guanosin 5'-(β , γ -imido)triphosphate (GppNHp) and guanosin 5'-O-(3-thio)triphosphate (GTP γ S), as well as fluoride ions and forskolin, enhanced the olfactory cilia enzymatic activity, while guanosin 5'-O-(2-thio)diphosphate (GDP β S), a GDP analogue, was inhibitory (Fig. 1b). Thus, the basic properties of olfactory adenylate cyclase are similar to those of hormone- and neurotransmitter-stimulated enzymes in other tissues¹⁷⁻¹⁹.

An important criterion for a functional role of adenylate

Fig. 1 *a*, Adenylate cyclase activity of frog olfactory cilia compared with that of membranes derived from other frog tissues. Open bars, basal activity levels; hatched bars, activity stimulated by 10 μ M GTP γ S (10 μ M GppNHp for turkey erythrocytes). OC, olfactory cilia preparation; OEM, membranes from deiliated olfactory epithelium; OE, membranes from whole olfactory epithelium; BM, membranes from brain; RC, respiratory cilia preparation; TE, turkey erythrocyte membranes. *b*, Activation of olfactory cilia adenylate cyclase by various effectors: BAS, basal activity; FORS, forskolin (10 μ M); GTP (10 μ M); FLU, sodium fluoride (10 mM); GppNHp (10 μ M); GTP γ S (10 μ M); GDP β S (1 μ M). *c*, Effect of odorants and other compounds on olfactory cilia adenylate cyclase in the presence of 10 μ M GTP. The results are normalized with respect to activity elicited by GTP alone (G), which is about twice the basal activity level; MX, equimolar mixture of the four indicated odorants (Aldrich) at 0.25 mM each: AA, *n*-amyl acetate; CN, 1,8-cineole; CV, L-carvone; CT, citral (a mixture of *cis* and *trans* isomers); each at 1 mM. ISO, isoprenaline (isoproterenol); PGE, prostaglandin-E₁; HIS, histamine, at log molar concentration as indicated. The lower concentration is in the appropriate physiological range, the higher is for comparison with the maximal odorant concentration used. Error bars in *b* and *c* (as in all following figures) represent standard deviation. Standard deviations in *a* are $\pm 15\%$ in any given preparation and up to $\pm 30\%$ between preparations. However, this larger error in absolute specific activities does not affect the activity ratios expressed in *b* and *c*.

Methods. Frogs (*Rana ridibunda*) were used for cilia preparation as described elsewhere^{10,11}. Briefly, epithelia were dissected and exposed to a 'calcium shock' by abruptly increasing Ca^{2+} from $<1 \mu\text{M}$ to 10 mM. Two steps of differential centrifugation yielded a preparation containing $>80\%$ cilia fragments and membrane vesicles derived from them. Membranes from various frog tissues were prepared by a simplified procedure in which tissue was polytron-homogenized (30 s, 0°C) in 20 mM Tris-HCl, pH 8.0, saturated with phenylmethylsulphonyl fluoride (PMSF). After removal of tissue and intact cells by centrifugation at 500g and 1,700g, respectively, membranes were precipitated at 20,000g. Turkey erythrocyte membranes were prepared as described previously³². Cilia and membranes were stored at -70°C or -180°C and aliquots frozen and thawed only once to keep adenylate cyclase activity intact. Adenylate cyclase was assayed as described previously²⁷ in the presence of 0.5 mM 3-isobutyl-1-methyl xanthine (IBMX). Protein content of samples was measured by the method of Bradford³⁸, with bovine serum albumin as a standard.

cyclase activity in olfaction would be its modulation by odorous compounds in a cell-free system²⁴. To maximize the probability of observing an effect, experiments were carried out with a mixture of four odorants (citral, L-carvone, 1,8-cineol and *n*-amyl acetate), all shown electrophysiologically to be detected by the frog olfactory system^{7,8,13,25-27}. This odorant mixture enhanced the adenylate cyclase activity of olfactory cilia in a dose-dependent manner (Fig. 2a). Activation was already significant at 2.5 μM of individual odorants. In several independent experiments, the maximal activation achieved at 0.25 mM of individual odorants was to 4.6 ± 0.8 of the basal value (2.3 ± 0.4 of the GTP-stimulated level). Odorant stimulation was seen only in the presence of GTP, suggesting dynamic regulation requiring GTP hydrolysis, while GTP γ S stimulated the enzyme maximally, eliminating the odorant effect (Fig. 2a). This behaviour is similar to that of other receptor-modulated adenylate cyclase systems¹⁷⁻¹⁹.

The following findings constitute additional evidence for the specificity and physiological relevance of the *in vitro* odorant response. (1) Odorants did not activate adenylate cyclase in membranes from unrelated tissues, for example, frog brain (Fig. 2b) or frog liver (not shown). (2) Although the odorants, either in mixture or individually applied, enhanced adenylate cyclase activity of olfactory cilia to various degrees, compounds known to be stimulatory in other membranes are ineffective (Fig. 1c). (3) The maximal *in vitro* odorant effect occurred at concentrations of organic compounds 10–100 times lower than those required for nonspecific modulation of adenylate cyclase via changes in membrane fluidity²⁸. (4) The odorant concentrations necessary to stimulate adenylate cyclase *in vitro* (a cell-popula-

tion response) correlated well with those known to give measurable *in vivo* summated electrophysiological recordings. Such recordings are typically carried out at 10^{-2} – 10^0 vapour saturation²⁵⁻²⁷ for odorous compounds respectively having vapour pressures of 5–0.05 mm Hg (at 25°C)^{25-27,29}. With molar water/air partition coefficients being in the range 1–1,000 (ref. 30), the physiological aqueous odorant concentrations would be 3×10^{-6} – 3×10^{-3} M, in good agreement with our experiments. (5) The low value (<0.5) of Hill slope for the *in vitro* odorant response (Fig. 2a) agrees well with the slopes of electrophysiological and psychophysical dose-response curves (see ref. 27). As similar *in vitro* values were also obtained for a single odorant (amyl acetate, not shown), the low Hill slope probably arises from receptor heterogeneity^{9,11,13,14}, which would also explain why saturation is not observed within the concentration range examined. Our finding that diverse ligands stimulate ciliary adenylate cyclase is also consistent with such receptor heterogeneity.

Inherent problems in the application of classical receptor binding techniques to olfactory research^{12,13} include the lack of defined pharmacological profiles and specific antagonists for individual receptor types, and the absence of 'negative controls' (odorant homologues that do not cause activation). These problems may at least partially be related to receptor heterogeneity, and could be alleviated by the future development of olfactory neuronal cell lines possessing defined odorant specificity¹⁴. Measurements of odorant-stimulated adenylate cyclase could help in the study of such cells.

The dependence of olfactory adenylate cyclase activity on guanine nucleotides suggests that a signal-transducing G-protein

Fig. 2 Effect of odorants at increasing concentrations on adenylate cyclase activity in frog olfactory cilia (a) and frog brain membranes (b). Zero on abscissa means no odorants. GTP concentration is 10 μ M in both, GTP γ S concentration is 10 μ M in brain membranes and 1 nM in olfactory cilia. The lower curve in a and b is with no guanine nucleotides. Hill coefficients for the odorant response were calculated as the average slope of a graph of $\log Y/(1-Y)$ against $\log$ odorant concentration, where Y is the fraction of maximal stimulation attained. Maximal activation values from 55 to 80 nmol cyclic AMP per mg protein per min were used, to give a range of Hill coefficients of 0.35–0.49.

is involved, similar to the hormonal G-proteins^{17–19} and to visual transducin^{15,16}. To identify this protein, olfactory cilia were subjected to ³²P-ADP-ribosylation catalysed by bacterial toxins (Fig. 3). The cilia were found to contain a cholera toxin labelled polypeptide of relative molecular mass (M_r) 42,000 (42K) and a pertussis toxin labelled polypeptide of 40K. The first polypeptide has properties similar to those of the hormonal stimulatory G-protein (G_s), whereas the second is more like the inhibitory G-protein (G_i) or transducin^{15–19,31,32}. The polypeptide similar to G_s was found to be highly enriched in the cilia compared with membranes from deciliated epithelium, while the G_i -like protein is not (Fig. 3). This, together with the fact that odorants and GTP γ S increase rather than decrease ciliary adenylate cyclase activity, suggest that the G_s -like protein is the specific neuronal membrane component responsible for receptor-cyclase coupling. The possible slight difference in M_r between the ciliary and liver G_s (Fig. 3), and the observation (Fig. 2a) that olfactory adenylate cyclase can be fully activated by GTP γ S at much lower concentrations (1 nM) than those necessary for its hormonal counterpart (1–10 μ M, ref. 32), may imply that the olfactory G-protein is a distinct G_s variant.

Additional evidence for the involvement of a G-protein in olfactory reception could be obtained from studies of the interaction between the ligand-activated receptor and the ADP-ribosylation site on the G-protein, as shown for visual and some hormone receptors^{33,34}. Our preliminary evidence (U.P. and D.L., unpublished) suggests that the toxin-catalysed modification of the ciliary G-protein synergizes with odorants in the activation of adenylate cyclase. More research is needed to resolve this issue.

The present study provides a direct identification of molecular components involved in olfactory reception. The enzyme adenylate cyclase is shown to be present in high amounts in the olfactory neuronal dendrites, and its activity is specifically enhanced by functional ligands in a cell-free system. These results, together with the previously reported *in vivo* modulation of olfactory responses by cyclic AMP analogues and phosphodiesterase inhibitors^{21,22}, provide all the criteria²⁴ necessary for establishing the role of cyclic AMP as a second messenger in olfactory reception. Measurements of odorant-stimulated adenylate cyclase in olfactory cilia thus provide the first *in vitro* assay for olfactory reactivity, and could complement electrophysiological recordings in the study of odorant recognition.

Our results suggest that the putative olfactory receptor molecules^{6–14} activate a cyclic nucleotide modulating enzyme

Fig. 3 SDS polyacrylamide gel electrophoresis autoradiography patterns of olfactory cilia (C), deciliated olfactory epithelial membranes (E), liver membranes (L) and retinal rod outer segments (R), all from frog, after ³²P-ADP-ribosylation in the absence (NTX) or presence of *Vibrio cholerae* toxin (CTX) or islet activating protein, *Bordetella pertussis* toxin (PTX) (both from List Biological Laboratories, Campbell, California). Silver staining patterns (SIL) are also shown, to indicate the relative amount of material used for labelling. ADP-ribosylation was carried out by a procedure similar to that of Schleifer *et al.*³⁹. Membranes (200 μ g ml⁻¹) were reacted at 37 °C in 20 mM Tris-HCl (pH 7.6) in the presence of 30 mM thymidine, 1 mM ATP, 0.1 mM GTP, 5 mM MgCl₂, 1 mM EDTA, 1 mM dithiothreitol (DTT), 5 μ M ³²P-NAD⁺ (NEN, 10–20 Ci mmol⁻¹), 3 mM phosphoenolpyruvate, 5 U ml⁻¹ pyruvate kinase, 0.05% Triton X-100. The reaction was stopped after 1 h by adding electrophoresis sample buffer and boiling. The toxins (10 μ g ml⁻¹) were activated by preincubation with 20 mM DTT at 37 °C for 15 min. M_r standards ($\times 10^{-3}$) are marked; G_s , G_i , the positions of the heavy (α) chain of the stimulatory and inhibitory G-proteins; T, heavy (α) chain of visual transducin. The left part of the figure is a more heavily labelled autoradiogram showing that, for comparable amounts of silver-stained protein, the cilia contain much more cholera toxin substrate than do epithelial membranes, but both have similar amounts of pertussis toxin substrate. No labelling is seen in either preparation when toxins are absent. The right part of the figure is lightly loaded and exposed, and is intended to provide a more accurate definition of the labelled polypeptides. Olfactory cilia have a single cholera toxin polypeptide substrate, which seems to co-migrate with a similarly labelled polypeptide in frog liver. Both migrate at about 0.85 of the distance between the carbonic anhydrase (M_r 31K) and ovalbumin (43K) standards, similar to the major cholera toxin substrate found in most other tissues and species^{18,40}. This polypeptide is named 42 K or 45K (we use the former) depending on the relative molecular mass assignment for the ovalbumin standard (43K or 45K–46K)⁴⁰. The olfactory preparations do not contain a 52K cholera toxin substrate, which is seen in some tissues and species and migrates more slowly than the ovalbumin standard⁴⁰. A weak band appearing below the 42K species in the leftmost lane may be a minor proteolytic cleavage product, and is seen occasionally in overloaded electrophoretograms. The pertussis toxin substrate of olfactory cilia is seen to be a doublet of polypeptide bands. The heavier component migrates between visual transducin and the G_i α -chains, and is putatively identified as the 40–41K polypeptide commonly ascribed to G_i α -chain^{18,40}. The lighter component almost co-migrates with transducin (39K). Multiple forms of pertussis toxin labelled polypeptides have been reported recently in nervous tissue^{41,42}.

via a GTP-binding signal-transducing protein. Olfaction thus appears to bear a striking molecular similarity to hormone, neurotransmitter and visual reception^{15–19}. This similarity can be used to clarify some aspects of olfactory function such as the role of transducing enzyme cascades in chemosensory signal amplification (see ref. 15). In parallel, olfaction may be viewed as a model for other molecular recognition processes. The fact that olfactory cilia preparations contain practically pure dendritic membranes derived from a single neuronal class, and are highly enriched in transducing components, make them suitable for studying general aspects of signal transfer in neuronal membranes.

The resemblance between olfaction and other transmembrane signalling mechanisms probably also applies to the receptor

molecules themselves. Thus, olfactory receptors may be integral membrane glycoproteins¹⁴ that interact with G-protein(s), as are the β -adrenergic receptor³⁵ or rhodopsin¹⁶. Such clues should be useful in devising new strategies for olfactory receptor studies. Accordingly, we are now examining the effect of lectins and monoclonal antibodies against defined ciliary surface glycoproteins^{11,36} on ciliary adenylate cyclase activity, and studying the direct association of glycoprotein receptor candidates with olfactory G-proteins.

This research was supported in part by grants from the United States-Israel Binational Science Foundation (Jerusalem), the Fund for Basic Research administered by the Israel Academy of Sciences and Humanities, the Minerva Foundation and NINCDS (N222063) to D.L., an incumbent of the Recanati Career development chair. Y.S. is the Charles W. and Tillie Lubin professor of Hormone Research. We thank Dr Ora Kedem for continuous support and encouragement.

Vaccination with purified microgamete antigens prevents transmission of rodent malaria

P. G. Harte, N. Rogers & G. A. T. Targett

Department of Medical Protozoology, London School of Hygiene and Tropical Medicine, Gower Street, London WC1E 7HT, UK

Malaria vaccination with preparations of microgametes has been shown to inhibit transmission of *Plasmodium* spp. to the mosquito vectors of avian^{1,2}, rodent³ and simian^{4,5} parasites. This transmission-blocking immunity results from the induction of microgamete-agglutinating antibodies in the vaccinated host which, when ingested in a mosquito blood meal, react with exflagellating microgametes in the midgut to prevent fertilization and oocyst development. Here we have passively transferred the immunity with gamete-specific monoclonal antibodies raised against the rodent malaria parasite *Plasmodium yoelii nigeriensis*⁶, and an IgG2a isotype monoclonal antibody from a hybridoma cell line, PYG-1, has been used to identify the target antigens on the gametes and to affinity-purify sufficient quantities of specific gamete antigen to facilitate vaccination studies. This transmission-blocking monoclonal antibody immunoprecipitated microgamete antigens of apparent relative molecular mass (M_r) 67K (67,000), 59K, 57K, 42K and 35K. Immunization of mice with these proteins before infection and mosquito feeding led to a 85-99.7% reduction in transmission to the mosquito vector; vaccination via intravenous or intramuscular routes was equally effective and did not require an adjuvant.

Gametocytes were purified from blood infected with *P. yoelii nigeriensis* by centrifugation through a discontinuous Percoll gradient⁷, washed and stimulated to undergo gametogenesis¹. After exflagellation, the soluble male gamete antigens were applied to an affinity column of transmission-blocking monoclonal antibody PYG.1 coupled to a Sepharose 4B matrix, washed through and the bound protein was eluted (see Fig. 1 legend).

Table 1 Vaccination with purified microgamete antigens prevents transmission of malaria

Group	Dose (μ g)	Route of administration	Mean no. oocysts per mosquito (range)	No. mosquitoes infected/total
1	40	i.v.	13 (0-60)	37/50
	40	i.m.	33 (0-120)	46/50
2	40, 30	i.v.	1 (0-7)	15/50
	40, 30	i.m.	2 (0-14)	18/50
Controls	—	—	350	60/60

Two groups of female BALB/c mice were injected i.v. or i.m. with 40 μ g of affinity-purified gamete antigen (see Fig. 1 legend). Two more groups of mice were immunized i.v. or i.m. with 40 μ g of soluble gamete antigen, followed 2 weeks later by a second dose of 30 μ g administered via the same route as the priming dose. All mice were infected i.v. with 10⁶ *P. y. nigeriensis*-infected erythrocytes 14 days after the final immunization. Three days after infection, batches of mosquitoes were fed for 30 min on each group of mice. Mosquitoes were maintained at a temperature of 24-27 °C for 1 week, before dissection and microscopic examination of their midguts for oocysts. All mosquitoes fed on control mice were heavily infected with oocysts; a random sample of 5 mosquitoes revealed a mean of 350 oocysts per mosquito.

SDS-polyacrylamide gel electrophoresis (PAGE) (Fig. 1) revealed that the monoclonal antibody immunopurified one major antigen of apparent M_r 42K and a series of minor proteins of M_r 67K, 50K, 57K and 35K. These proteins are specific to the sexual stage of the parasite; no bands were eluted from a PYG.1 column after application of solubilized asexual-stage parasites.

Female BALB/c mice were immunized as follows. Two groups of mice were each injected with a single 40- μ g dose of purified gamete antigen either intravenously (i.v.) or intramuscularly (i.m.), while two other groups of mice were immunized with 40 μ g of gamete antigen by the i.v. or i.m. route, followed 2 weeks later by a second dose of 30 μ g injected as per the priming dose.

Fig. 1 SDS-PAGE analysis of *P. y. nigeriensis* gamete antigens. Lane a, M_r markers; lane b, total gamete antigen profile; lane c, PYG.1 affinity-purified gamete antigens.

Methods. Mouse blood with a gametocytaemia of 0.5–1.5% (parasitaemia 40–60%) was washed in suspended animation (SA) medium (0.21% Tris, 0.96% NaCl, 0.2% glucose, pH 7.4), in which gametogenesis is reversibly suppressed, and the gametocytes were purified by centrifugation through a discontinuous Percoll (Sigma) gradient as described in ref. 7. The gametocyte-enriched fraction was washed in SA medium and resuspended in gamete-releasing medium (2.5 vol. 5% NaCl, 2.5 vol 10% glucose, 20 vol 1.46% NaHCO_3 and 100 vol. heat-inactivated fetal calf serum adjusted to pH 8.0; ref. 1). After exflagellation, the male microgametes were separated by differential centrifugation and pelleted at 13,000g. Microgamete antigens were extracted on ice in 10 vol. of solubilizing medium (50 mM Tris pH 8.2 containing 1% Nonidet P-40, 5 mM EDTA, 5 mM EGTA, 5 mM iodoacetamide, 1 mM phenylmethylsulphonyl fluoride and 0.1 mM TLCK). Insoluble material was removed by centrifugation at 100,000g for 30 min at 4°C. The soluble gamete antigens were applied to an affinity column of transmission-blocking monoclonal antibody PYG.1 coupled to a Sepharose 4B matrix equilibrated with 10 mM Tris pH 8.0 containing 0.5 M NaCl and 5% (v/v) solubilizing medium. The column was washed with equilibrating buffer and the bound protein eluted with 50 mM diethylamine (pH 11.5) into tubes containing 1 M Tris pH 8.0. After neutralization, dialysis and concentration, the affinity-purified antigen was reappplied to the column and the affinity-purification procedure repeated. After further dialysis and concentration, the affinity-purified antigens were analysed by SDS-PAGE on 10% gels. Storage before use was at -30°C .

Sera taken from mice 10 days after a second i.v. or i.m. vaccination produced immunofluorescent staining patterns, using formalin-fixed whole gametes, which were indistinguishable from those produced by the monoclonal antibody PYG.1 (data not shown). Furthermore, using a combination of Western blot analysis and enzyme-linked immunosorbent assay techniques, these sera were found to react with a single gamete polypeptide of apparent M_r 42K, similar to the major protein in the affinity-purified gamete antigen preparation (Fig. 2), and thus confirming the immunogenicity of the affinity-purified antigen.

To determine whether immunization induced effective transmission-blocking immunity, all mice were injected i.v. with 10^6 *P. y. nigeriensis*-infected erythrocytes 14 days after the final immunization, and mosquitoes were fed on them 3 days later. The mosquitoes were maintained at 24–27°C for a further 7 days before dissection and enumeration of oocysts in the midguts. The results (Table 1) show that immunization with a single dose of antigen led, respectively, to a 95% (i.v. route) and 85% (i.m.) reduction in oocyst numbers relative to mosquitoes fed on unvaccinated animals. Animals given two doses

Fig. 2 Western blot analysis of *P. y. nigeriensis* gamete antigens. Solubilized unfractionated whole gamete proteins were separated by SDS-PAGE on a 10% gel and transferred electrophoretically to a nitrocellulose membrane. After blocking with 5% (w/v) bovine serum albumin in phosphate-buffered saline, the nitrocellulose membranes were incubated for 45 min with sera (diluted 1:100 in phosphate-buffered saline) taken from mice immunized i.v. or i.m. with affinity-purified gamete antigen. The membranes were washed and incubated with peroxidase-conjugated rabbit anti-mouse immunoglobulin for 45 min. The strips were then washed and stained with the substrate diaminobenzidine. The estimated M_r of the polypeptide is indicated.

of vaccine via the i.v. or i.m. routes were found to be almost totally uninfected to feeding mosquitoes, with oocyst numbers reduced by 99.7% and 99.3%, respectively. Indeed, more than two-thirds of mosquitoes in the latter groups were found to be uninfected. The transmission-blocking immunity was stage-specific in that no significant protection against the asexual erythrocytic forms of the disease was noted in any of the vaccinated animals (data not shown).

Although it is well documented that specific monoclonal antibodies directed against the sexual stages of *Plasmodium* will effectively block transmission of the parasite to its mosquito vector^{6,8–10}, this is the first report of purified soluble gamete antigens inducing an effective transmission-blocking immunity. The immunity is potent and does not require the co-administration of an adjuvant.

The mechanisms by which the host immune system mediates suppression of transmission appears to be serum-mediated (Fig. 2), as suggested by others^{2,6,10}. Microgametes are only susceptible to the action of the immune system immediately after exflagellation, and it is likely that the antibodies raised against the soluble antigen act to agglutinate gametes in the mosquito gut, preventing fertilization and consequently the transmission of infection.

This investigation received financial support from UNDP/World Bank/WHO special Programme for Research and Training in Tropical Diseases, and from the Wellcome Trust through the Eurogamete Collaborative Programme.

A uniform deleting element mediates the loss of κ genes in human B cells

Katherine A. Siminovitch, Ajay Bakhshi, Paula Goldman & Stanley J. Korsmeyer

Metabolism Branch, Bldg 10 Rm 4N-114, National Cancer Institute, National Institutes of Health, Bethesda, Maryland 20205, USA

Human immunoglobulin light-chain genes become rearranged in an ordered fashion during pre-B-cell development such that rearrangement generally occurs in κ genes before λ genes (refs 1, 2). This ordered process includes an unanticipated deletion of the constant κ (C_κ) gene and κ enhancer sequence which precedes λ rearrangement¹⁻⁴, and the site of this deletional recombination was located 3' to the joining (J_κ) segments in 75% of cases studied. We have now characterized the recombinational element responsible for this event on three separate alleles and found them to be identical. This κ -deleting element recombined site-specifically with a palindromic signal (CACAGTG) located in the J_κ - C_κ intron. All losses of C_κ genes in other human B cells were mediated by this determinant, including the 25% of instances when this element recombined with sequences 5' to J_κ . In contrast, the κ -deleting element remained in its germline form on all successful κ -producing alleles. Moreover, κ loss is an evolutionarily conserved event, as the κ -deleting element appears to be the human homologue of the murine RS sequence⁵. Our results suggest that this element may help ensure isotypic and allelic exclusion of light chains and may be involved in the ordered use of human light-chain genes.

The two available light-chain classes in humans are used almost equally (κ , 60%; λ , 40%), yet the gene configuration of the excluded light-chain class in κ - and λ -producing B cells shows a marked dichotomy. Clonal cell lines or leukaemias of κ -producing B cells usually retain germline λ genes. In contrast, λ -producing B-cell lines have no remaining germline κ genes, at least the C_κ portion having usually been deleted³. Deletion of the κ genes is a normal developmental event unrelated to transformation⁶, and our examination of B-cell precursors indicated that this deletional event can occur before λ gene rearrangement^{1,2,4}. We further investigated the extent of the κ deletion and found that the C_κ region and the κ enhancer element

Fig. 2 Restriction map analysis, sequencing strategy and nucleotide sequence of the germline J_κ - C_κ region and three rearranged alleles bearing the 3' rearrangement. **a**, The germline J_κ - C_κ region restriction map in which arrows indicate sequencing strategy for M13 subclones sequenced by the Sanger dideoxy termination method³⁰. Three rearranged alleles (**b**, **c**, **d**) were cloned from *Bam*HI-digested (**b**, **c**) or *Eco*RI-digested (**d**) genomic DNA that was size-selected by preparative gel electrophoresis, ligated into the phage vectors Charon 28 or Charon 4A, and successfully screened with a J_κ segment probe^{25-27,31}. **b** is an 11.5-kb *Bam*HI J_κ -containing allele, **c** is an 8.8-kb *Bam*HI J_κ -containing allele from Nalm-6, while **d** is a 10-kb *Eco*RI J_κ -containing allele from Reh. In all three alleles a uniform κ -deleting element (κ de) has been introduced at their 3' end (open box), and all have undergone a separate rearrangement on the 5' side of J_κ . Nucleotide sequence analysis revealed the palindromic heptamer (CACAGTG) at 917 base pairs 3' to J_κ 5 in the germline J_κ - C_κ intron (**e**). The nucleotide sequence of the introduced κ de is identical in the Nalm-11.5 and Reh-10 alleles. Their recombination breakpoints are focused around the palindromic sequence. H, *Hind*III; B, *Bam*HI; P, *Pst*I; S, *Sac*I; E, *Eco*RI; X, *Xho*; Sm, *Sma*I.

were uniformly lost from the genome in all 20 instances examined (Fig. 1, Table 1). This was true for all deletions of κ genes in λ -bearing B cells, pre-B cells and those instances in which the excluded κ allele in κ -producing B cells was lost (Fig. 1, Table 1). All J_κ segments were also deleted in 5 of 20 instances, but were retained in a rearranged state in 15. Previous

Fig. 1 Deletions of J_κ and C_κ regions in human B cells. Representative genomic blots are presented of *Bam*HI-digested DNA which was electrophoresed in parallel on the same agarose gel, transferred to nitrocellulose paper, then hybridized with the indicated probes²⁵⁻²⁷. A human placenta served as a germline control, LY67 is a μ , λ -producing Burkitt lymphoma cell line²⁸, Nalm-6 and Reh are B-cell precursor acute lymphoblastic leukaemia cell lines² and SU-DHL-6 is a μ , κ -producing diffuse histiocytic lymphoma cell line²³. A 2.5-kb *Eco*RI genomic fragment was used as a C_κ probe and a 1.8-kb *Sac*I germline genomic fragment was used as a J_κ probe²⁹. Dash marks indicate the germline position and arrows denote rearrangements. A 0.7-kb *Eco*RI fragment containing the enhancer sequence revealed that the κ enhancer region was also deleted each time C_κ was lost (data not shown). Cytogenetic analysis of these cell lines revealed no translocations or obvious deletions of the short arm of chromosome 2. Asterisks indicate probes used in hybridization.

We examined three additional pre-B cells, Nall-1, ALL-RT-5 (ref. 2) and RS 4; 11 (ref. 22); four κ -producing B cells, CLL-RT, SU-DHL-4 (ref. 23), BHM23, SU-DHL-7 (ref. 23); three λ -producing B cells, SU-DHL-5 (ref. 23), RPMI 8392 (ref. 24) and CLL-DG; and two non-producing B-cell lines, SU-DHL-2 (ref. 23) and VDS. *Bam*HI-digested genomic DNA from individual cells was electrophoresed in parallel on the same gel and then hybridized to the previously described C_{κ}^* and J_{κ}^* probes, to a 0.7-kb *Eco*RI fragment containing the enhancer sequence (E_{κ}^*)¹⁷, and to the 2.5-kb *Hind*III/*Bam*HI κ -deleting element (κde^*) probe. Whenever the enhancer to C_{κ} ($E_{\kappa}-C_{\kappa}$) regions were deleted, the J_{κ} segments were found to be rearranged onto the same *Bam*HI fragment as the κde ($J_{\kappa}/\kappa de$). When the J_{κ} , E_{κ} and C_{κ} regions ($J_{\kappa}-C_{\kappa}$) were deleted, the κde was always rearranged to sequences apparently 5' to J_{κ} (5' sequence/ κde). In contrast all alleles with rearrangements limited to the 5' side of J_{κ} retained the E_{κ} and C_{κ} regions and were presumably attempts at V/J joining ($V/J_{\kappa}-C_{\kappa}$). These rearrangements always retained a germline κde .

studies indicated that one variable-region (V_{κ}) gene family was retained in its germline state³. We reasoned that cells in which the J_{κ} region was rearranged while the enhancer and C_{κ} region were deleted represented an opportunity to identify a 3' element that was being introduced by this deletion recombination. Therefore, we cloned the rearranged J_{κ} alleles from the B-cell precursor lines Nalm-6 and Reh.

Both rearranged J_{κ} alleles from Nalm-6 and one rearranged J_{κ} allele from Reh were isolated from these pre-B-cell lines and compared with the germline $J_{\kappa}-C_{\kappa}$ region (Fig. 2). Restriction map analysis indicated that all three J_{κ} alleles had undergone a 5' rearrangement, presumably from attempts at V/J joining^{7,8}. Furthermore, all three J_{κ} alleles had undergone a 3' rearrangement which introduced a uniform element into the $J_{\kappa}-C_{\kappa}$ intron. DNA sequence analysis of the new 3' element from both cell lines confirmed that they were identical (Fig. 2). We term this introduced sequence the κ -deleting element (κde). As these three examples of a rearranged κde seemed to be recombining within a limited region of the $J_{\kappa}-C_{\kappa}$ intron (Fig. 2), we sequenced this previously uncharacterized portion of the germline $J_{\kappa}-C_{\kappa}$ intron, searching for a site-specific target for recombination. At 917 base pairs 3' to the last J_{κ} segment ($J_{\kappa}5$), we noted the palindromic heptanucleotide (CACAGTG). Interestingly, this is identical to the heptamer flanking germline V and J regions which is presumably involved in V/J joining⁹⁻¹¹. The Nalm-11.5 allele rearranged precisely at this palindrome and the Reh-10 allele rearranged at or near it (Fig. 2). This suggests that the introduction of the κde into the $J_{\kappa}-C_{\kappa}$ intron uses a site-specific recombination mechanism.

We found that this uniform κ -deleting element mediated the

loss of C_{κ} regions in all other instances that we examined. A 2.5-kilobase (kb) *Hind*III/*Bam*HI fragment prepared from the κde of Nalm-11.5 recognized a unique 14-kb *Bam*HI genomic fragment in its germline form (Fig. 3). The germline position of the deletion element is thus clearly separate from the germline $J_{\kappa}-C_{\kappa}$ *Bam*HI fragment. Figure 3 and Table 1 indicate that there is a rearrangement of this κde on every allele in which C_{κ} is deleted. In all instances in which C_{κ} is deleted but the J_{κ} segment is retained, the κde can be shown to co-occupy the same *Bam*HI restriction fragment with the J_{κ} segment. This is true not only in Nalm-6 and Reh, from which the κde was cloned, but also for 12 other alleles (Fig. 3, Table 1). Furthermore, one allele of the κde is always rearranged in those instances in which the J_{κ} as well as the enhancer and C_{κ} segment are deleted. One allele in LY67 and SU-DHL-6 demonstrate this in Fig. 3, and further examples are noted in Table 1. This indicates that the κde has a target site(s) 5' to J_{κ} as well as within the $J_{\kappa}-C_{\kappa}$ intron. In contrast, κ -producing cell lines always retain a germline configuration of the κde on the expressed allele, as illustrated by B-85, SU-DHL-6, CLL-RG, SU-DHL-4, BHM23 and SU-DHL-7 (Fig. 3, Table 1). In approximately 25% of cases, even κ -producing B cells display a deletion of the phenotypically excluded κ allele. In these cells, as shown by B-85, SU-DHL-6 and BHM23, the κde is also responsible for the elimination of κ genes. Thus, this same κde accounts for all losses of C_{κ} genes observed in pre-B cells, λ -producing B cells and κ -producing B cells.

Rearrangement and elimination of κ genes in λ -producing B cells is an evolutionarily conserved event^{5,12-14}. Even though the mouse expresses λ on only 5% of its B cells, the C_{κ} regions of

Fig. 3 Rearrangement of the κ -deleting element (κ de) in human B cells. Representative genomic blots of co-migrated *Bam*HI-digested DNA that was hybridized with the C_{κ} , J_{κ} and enhancer (E_{κ}) probes as well as a 2.5-kb *Hind*III/*Bam*HI fragment of the κ de (cross-hatched bars) from the 11.5-kb allele of Nalm-6. Dash marks indicate the germline position and arrows denote rearrangements. On alleles in which only the C_{κ} and E_{κ} regions have been deleted, the J_{κ} region co-occupies a *Bam*HI fragment with the rearranged κ de (LY67, Nalm-6, Reh). On alleles in which the entire J_{κ} - C_{κ} region is deleted, the κ de is also rearranged (LY67, SU-DHL-6). On the productive κ -producing allele of B-85 and SU-DHL-6, the J_{κ} and C_{κ} segment co-occupy a rearranged *Bam*HI fragment, but the κ de remains germline.

these cells have frequently been deleted. Durdik *et al.* have identified an element that recombines with the identical conserved palindrome (CACAGTG) within the J_{κ} - C_{κ} intron of the mouse⁵. This is the same intron heptamer that underwent a 5' rearrangement with a V_{κ} region in MPC11, resulting in a truncated κ -chain product^{15,16}. However, the major role of this signal appears to be as an acceptor site for the κ de, resulting in the removal of the C_{κ} and enhancer region. This heptamer also flanks germline V and J regions, suggesting that the recombinatorial enzymes that help activate this gene (V/J joining) also mediate its destruction.

The use of a κ -deleting element in two species suggests strongly that it has a functional role. By removing the κ possibility, the κ de might ensure λ gene utilization. Moreover, all κ de rearrangements result in the elimination of the κ enhancer element^{17,18}. Studies with a pSV2-CAT construct have suggested that only a limited quantity of a *trans*-acting factor recognizing that enhancer exists in host cells¹⁹. Thus, the deletion of the κ enhancer may transfer the effect of an immunoglobulin enhancer-specific factor to a putative enhancer within the λ locus^{20,21}. Alternatively, either the germline or rearranged κ de may itself encode a *trans*-acting factor that affects λ gene rearrangement or transcription. The κ -deleting element may therefore mediate the ordered use of light-chain genes and help ensure that B cells make only one light chain of a selected light-chain class.

A molecular clone of HTLV-III with biological activity

Amanda G. Fisher, Enrico Collalti, Lee Ratner, Robert C. Gallo & Flossie Wong-Staal

Laboratory of Tumor Cell Biology, Developmental Therapeutics Programme, Division of Cancer Treatment, National Cancer Institute, Bethesda, Maryland 20205, USA

Acquired immune deficiency syndrome (AIDS) is an epidemic immunosuppressive disease characteristically associated with a depletion of T lymphocytes of the helper/inducer phenotype¹. Numerous converging lines of research have implicated a human T-cell lymphotropic retrovirus, HTLV-III, in the pathogenesis of AIDS²⁻⁵. Recently, several distinct forms of the HTLV-III genome were molecularly cloned in phage and extensively characterized^{6,7}. In the present study, a clone containing full-length HTLV-III proviral DNA⁷ was inserted into a plasmid and used to transfect cord blood T cells from normal newborn humans. We demonstrate that this molecular clone is infectious *in vitro* and causes marked cytopathic effects on T-cell cultures. This is the first direct evidence that the HTLV-III genome, rather than a minor component of the virus complex, is cytopathic for T cells. Using this biologically competent clone and mutants derived from it, it should now be possible to localize the subgenomic regions that contribute to the biological effects of HTLV-III.

Studies of cell-mediated immunity in AIDS victims reveal a generalized impairment of T-lymphocyte function accompanied by a reduction in T lymphocytes bearing the OKT4 antigen¹. The knowledge that a retrovirus (feline leukaemia virus) is often associated with severe immunodeficiency in cats⁸, and that the known human retroviruses are T-cell tropic and can impair immune function (see ref. 9 for a review), prompted speculation that a T-cell lymphotropic retrovirus might be the causal agent of AIDS. Two groups of human T-cell lymphotropic viruses,

Fig. 1 Construction of plasmids containing HTLV-III or HTLV-I proviral sequences. A 12.7-kb Xba I fragment derived from λ HXB-2D, a molecular clone containing ~ 10 kb of HTLV-III proviral sequences, was inserted into the Xba I site in the polylinker of plasmid pSP62²⁸. Similarly, a 13.7-kb Eco RI fragment of λ CH-1 (a molecular clone containing ~ 9.0 kb of HTLV-I proviral sequences)²⁹ was inserted into the Eco RI site of pSV2gpt³⁰. These plasmid constructs were then transfected into DH-1 bacteria and used in protoplast fusion experiments. The thin horizontal line represents HTLV-III (a) or HTLV-I (b) sequences; the solid boxes represent flanking cellular sequences; and the open boxes in c represent the long terminal repeat (LTR) regions of the molecular clone λ BH-10. BH-10 is an incomplete viral clone of HTLV-III which lacks a 190-base pair segment in the 5'-LTR and leader sequence⁷. Insert from this clone was used to prepare the probe for hybridization analyses.

HTLV-I and HTLV-II, have been characterized and their association with T-cell malignancies reported^{10,11}. Recently, a third distinct group of retroviruses has been repeatedly isolated from patients with AIDS or from those at risk for the disease^{3,12,13}. These retroviruses, designated by different groups as human T-cell lymphotropic virus type III (HTLV-III)³, lymphadenopathy-associated virus (LAV)¹², and AIDS-related virus (ARV)¹³, are variants of the same virus as shown by DNA sequence analyses¹⁴. Our laboratory has shown that circulating antibody to HTLV-III can be detected in sera from over 90% of AIDS patients and from a high proportion of people in various high-risk groups, but not from sera of healthy people in non-risk groups⁵. These results, together with demonstrations that HTLV-III has a cytopathic effect on OKT4-positive (OKT4⁺) cells¹⁵, clearly implicate HTLV-III in the aetiology of AIDS.

HTLV-III has many properties in common with HTLV-I and HTLV-II, including a propensity to infect OKT4⁺ lymphocytes, a reverse transcriptase that prefers Mg^{2+} , a major core protein of relative molecular mass 23,000–25,000 and immunological relatedness to some of the major viral proteins⁴. In addition, these viruses have in common the property of *trans*-acting transcriptional activation, probably mediated by a unique viral gene (*lor*) product^{16,17}. However, HTLV-III differs strikingly from other HTLV members in at least two important aspects: (1) HTLV-III is highly replicative *in vivo* and shows considerable genomic diversity⁷, and (2) normal T cells infected with

Fig. 2 Kinetics of cell growth and reverse transcriptase activity in cord blood mononuclear cell cultures following protoplast fusion. Mononuclear cells were prepared from cord blood samples using Ficoll Triosil and cultured for 5 days in media containing PHA. These cells were then fused with bacterial protoplasts carrying the plasmid pHXB-2D ($\circ/\bullet$), pSV2neo ($\Delta/\blacktriangle$) or pCH-1gpt ($\square/\blacksquare$) and maintained in culture at a density of 5×10^5 cells ml^{-1} by addition of RPMI-1640 medium containing 20% fetal calf serum, 10% T-cell growth factor (interleukin-2) and antibiotics. Three parallel fusions using cells from different individuals were established for each plasmid. In a, the growth of the transfected cells is expressed as the mean value for three fusion experiments. Spent medium removed from two cultures at 5, 11, 14 and 18 days after fusion was concentrated 10-fold and assayed for the presence of reverse transcriptase using standard techniques³¹. The activity detected in each of the culture supernatants is expressed (b) as the amount of ³H-labelled deoxyribonucleoside monophosphate (³H-dTMP) incorporated (in pmol per 0.3-ml sample) using dT₁₅·(rA)_n as the template primer.

Methods. Protoplast fusion: Single colonies of bacteria bearing the plasmid of interest were grown in L-broth containing ampicillin to a density of $2-4 \times 10^8$ ml^{-1} and chloramphenicol was added to a final concentration of 250 μg per ml of broth. After incubation at 37 °C for 2 h, gentamycin was added to 10 μg ml^{-1} and the cultures were re-incubated for 14–18 h to allow plasmid amplification. The bacteria were collected and resuspended in 2.5 ml of HEPES-buffered saline (HBS) pH 8.0, containing 20% sucrose. This suspension was placed on ice and at 5-min intervals, 0.8 ml of lysozyme solution (10 mg ml^{-1} in 0.25 M Tris-HCl pH 7.0), 1.0 ml of 0.25 M EDTA pH 8.0, and 1.0 ml of HBS were added sequentially. The suspension was incubated at 37 °C for 10–30 min until >90% of the bacteria had formed protoplasts, then held on ice and slowly diluted to 50 ml with RPMI-1640 medium. For each fusion, 10^{10} bacterial protoplasts were combined with 2.5×10^6 PHA-stimulated core blood cells, washed and the pellet resuspended in 0.1 ml of RPMI-1640 medium. To these cells, 0.8 ml of polyethylene glycol fusion reagent (PEG-FR) was added dropwise over 1 min, the cells were left to stand for a further minute and then gradually diluted with RPMI-1640. PEG-FR was prepared as a 48% solution in RPMI-1640 medium and was pretreated by passing it over a resin bed²². After fusion, the cells were washed and returned to culture.

Fig. 3 Demonstration of the presence of HTLV-III sequences in cord blood cell cultures transfected with pHXB-2D. **a**, DNA of high relative molecular mass was isolated from H9/HTLV-III_B cells (H9) and from cord blood cell cultures 14 days after transfection with pHXB-2D (CB¹⁴) using standard protocols³². H9/HTLV-III_B is a permanent human T-cell line which continuously produces large quantities of HTLV-III. DNA (5 µg) was either left undigested (lanes 1 and 2) or digested separately with the enzymes *Hind*III (lanes 3, 4), *Xba*I (5, 6) or *Bam*HI (7, 8), electrophoresed in standard 0.8% agarose gels, blotted and hybridized to probe prepared from nick-translation of the BH-10 insert. The filters were washed in 0.5×SSC, 0.1% SDS at 65°C for 4–6 h before exposure. **b**, A time-course study in which DNA from cord blood cells transfected with pHXB-2D was analysed for HTLV-III sequences 6, 11, 14, 18 and 31 days after protoplast fusion. DNA (5 µg) was digested with *Bam*HI and hybridized to the BH-10 probe (under the conditions described for **a**). DNAs prepared from H9/HTLV-III (H9) and from PHA-stimulated cord blood cell cultures (C) were included as positive and negative controls, respectively.

HTLV-III degenerate rapidly in culture. In contrast, although HTLV-I and HTLV-II exert some cytopathic effects, they are able to efficiently immortalize some of the infected T cells in *in vitro* co-culture^{18–20} and in cell-free²¹ transmission studies. The mechanism by which HTLV abrogates normal T-cell function, leading to transformation (in the case of HTLV-I/ HTLV-II) or death (in the case of HTLV-III), is unknown.

In the present study, we used a transfection technique to investigate the biological properties of molecularly cloned HTLV-III DNA. The phage clone λHXB-2D, which contains full-length integrated provirus (~10 kilobases, kb) with cellular flanking sequences (12.7 kb total length), was recently isolated in our laboratory from an H9/HTLV-III genomic library constructed using *Xba*I⁷. We inserted the 12.7-kb *Xba*I fragment from this clone into plasmid pSP62 (Fig. 1) and introduced this construct into phytohaemagglutinin (PHA)-stimulated lymphocytes using the protoplast fusion technique²². Plasmids containing full-length HTLV-I (pCH-Igpt) or no HTLV sequences (pSV2neo) were used as controls (Fig. 1).

Figure 2a summarizes the growth kinetics of T-cell cultures transfected with pHXB-2D, pSV2neo or pCH-Igpt. The growth of all cultures was comparable for the first 14 days after protoplast fusion. By day 18, however, the number of viable cells in cultures transfected with pHXB-2D had fallen dramatically; there was a 10-fold and a 100-fold reduction between days 18 and 21 and 18 and 32, respectively. Cultures transfected with either pSV2neo or pCH-Igpt showed only a 4–5-fold reduction over the same time period. When supernatant from the cultures was assayed for the presence of reverse transcriptase, activity was detected exclusively in cultures transfected with pHXB-2D (Fig. 2b). These data suggest that replicating virus was present in cultures 11–18 days after fusion with pHXB-2D protoplasts. The HTLV-I clone (pCH-Igpt) was apparently biologically inactive.

The presence of HTLV-III sequences in the transfected cells was demonstrated by Southern blot analysis (Fig. 3). DNA isolated from H9/HTLV-III_B was used as a positive control (H9). A 10-kb band, corresponding to unintegrated linear virus, was detected in undigested DNA samples prepared 14 days after transfection (Fig. 3a, lane 1). Digestion with *Xba*I revealed three distinct bands at 11, 10 and 5.2 kb; these co-migrate with bands frequently seen in undigested DNA from HTLV-III-infected H9 cells and other HTLV-III-infected cell lines and fresh tissues⁷ (Fig. 3a, lane 2). As *Xba*I does not cut within the viral sequences of clone pHXB-2D, these bands probably represent the nicked circular, linear and closed circular forms of unintegrated HTLV-III, respectively. In the *Xba*I-digested DNA samples, there was an increase in intensity of the nicked circular form compared with that in the undigested DNA sample (Fig.

3a, compare lanes 5 and 1); this was probably a result of nonspecific cleavage during incubation with the enzyme. The failure to demonstrate a DNA fragment of 12.7 kb shows that there was little or no plasmid carrying HTLV-III sequences in these cultures.

Digestion with *Hind*III, an enzyme which cuts the HTLV-III genome of pHXB-2D six times, yielded bands at 4.5, 2.0 (a doublet), 1.7 and 0.6 kb (a doublet) (Fig. 3a, lane 3), consistent with the fragments expected to be generated by *Hind*III digestion of linear unintegrated virus. This restriction pattern is clearly different from that of H9/HTLV-III_B (Fig. 3a, lane 4). The H9/HTLV-III_B cell line was derived from the human T-cell line HT, following co-culture with T lymphocytes obtained from several AIDS patients³, and contains many different HTLV-III forms. Thus, the differences in restriction patterns are consistent with H9/HTLV-III_B containing, as a minor component, a provirus equivalent to that of pHXB-2D. The major component of H9/HTLV-III differs, however, from the HTLV-III genome of pHXB-2D by the absence of a *Hind*III site ~3.5 kb from the 3' end of the virus⁷. *Bam*HI digestion of the DNA from the transfected cultures gave two fragments (8.6 and 1.5 kb) which result from a single cut of the linearized genome (Fig. 3a, lane 7). High-relative molecular mass 'smears' were not observed when DNA was digested with *Bam*HI. Therefore, we have no direct evidence that transfected HTLV-III DNA is integrated in the host cell genome. HTLV-III may integrate randomly and at too low a frequency to be detected by Southern blotting. Alternatively, it is conceivable that HTLV-III, like spleen necrosis virus and visna virus (cytopathic avian and ovine retroviruses), may not need to be integrated for virus production^{23,24}.

Expression of the HTLV-III gag-related proteins p15 and p24 by transfected cells was demonstrated using specific monoclonal antibodies (Fig. 4a–e): maximum expression was observed 18 days after transfection, when 4–11% and 5–9% of cells were reactive with antibody to p15 and p24, respectively (data not shown). Virus particles were detected by electron microscopy in all cultures 14–18 days after transfection with pHXB-2D (Fig. 4f). The particles contained condensed, truncated cores, which are characteristic of HTLV-III particles²⁵.

In time-course experiments (Fig. 3b), DNA isolated from a single culture 6, 11, 14, 18 and 31 days after transfection with pHXB-2D, was digested with *Bam*HI and analysed for HTLV-III sequences. Six days after transfection, an 8.6-kb DNA fragment was detected as a faint band; 18 days after transfection it was possible to detect a 1.5-kb DNA fragment in addition to the 8.6-kb fragment (Fig. 3b). The total amount of unintegrated virus in the cultures appeared to increase, as suggested by the increase in intensity of these bands with time; we interpret this as evidence that cells originally transfected with pHXB-2D are

Fig. 4 Expression of HTLV-III p15 and p24 antigens and the production of virus particles by cord blood cell cultures transfected with pHXB-2D. Indirect immunofluorescence studies were performed using monoclonal antibodies against the HTLV-III gag-related proteins p24 (a, d) and p15 (b, e) (ref. 33 and A. Bodner, unpublished observations). Cells were fixed for 5 min using a 1:1 mixture of acetone/methanol and standard techniques. d, e, Cord blood cells removed from culture 18 days after transfection with pHXB-2D and stained to reveal the binding of these antibodies. A small percentage (4–11%) of the cells clearly express HTLV-III p24 and p15 antigens. In comparison, among H9/HTLV-III cultures (a, b), a much larger proportion of cells (70–90%) was positive for p24 and p15. c, Cord blood cells removed 18 days after transfection with pCH-Igpt (HTLV-I clone) were not labelled by these antibodies. f, Electron micrographs of cord blood cell cultures transfected with pHXB-2D show the presence of extracellular HTLV-III virus particles in cultures 18 days after protoplast fusion ($\times 45,000$).

able to produce fully infectious virus which is then transmitted within the culture.

No HTLV-III sequences were detected 31 days after transfection (Fig. 3b); at this point the culture may have contained only cells which failed to be infected by HTLV-III. This result is again consistent with the transfected DNA exerting a cytopathic effect on T cells. The finding that, at any stage, only a minor population of the transfected cells are apparently infected by the virus (<15% express viral proteins) suggests that the cytopathic effects may not result solely from direct viral infection and that secreted factors and/or other cell-to-cell interactions may play a part in the cytopathic phenomenon. To confirm this, we are presently using an *in situ* RNA hybridization technique to accurately assess the proportion of cells expressing viral messenger RNA transcripts (as this may be higher than the proportion expressing p15 or p24) (A.G.F. *et al.*, in preparation).

We have described the construction of a molecular clone of HTLV-III and its introduction into normal T cells, and demonstrated that T cells transfected with this clone contain unintegrated HTLV-III proviral sequences, express viral antigen and produce mature virus particles. Furthermore, we provide evidence that the virus produced from the HTLV-III genome is infectious and has marked cytopathic effects *in vitro*. Thus, HTLV-III is itself pathogenic for normal T cells. These results exclude the possibility that a minor component of the virus

complex is solely responsible for, or acts as a co-factor in, the cytopathic effects. The availability of this clone will allow us to elucidate the biological functions of the HTLV-III genome and, in particular, to localize the regions governing the cytopathic properties of the virus. In addition, as transfection allows the introduction of viral DNA into cells not normally infected by HTLV-III, we can use this system to investigate whether the tropism displayed by HTLV-III is determined exclusively at the level of the receptor^{26,27} or also at an intracellular level.

We thank Drs G. Brown, E. Westin, B. Hahn, G. Shaw and P. Sarin for helpful discussions, and Drs M. Gonda, A. Bodner, L. Simek, M. Litsky and A. LoMonico for their assistance. This work was supported in part by grants to A.G.F. from The Lady Tata Memorial Research Fund.

Because monoclonal antibodies can recognize and bind to specific groups of atoms such as tumour antigens, they have promise for use *in vivo* as carriers of radionuclides, drugs or other appended molecules for diagnosis and treatment of disease^{1–3}. Attachment of metal ions to antibodies by means of bifunctional chelating agents can add the diverse nuclear, physical and chemical properties of the metallic elements to these specific binding proteins (ref. 4 and refs therein). With the ultimate aim of engineering

probe-binding properties into the antibodies themselves, we have now prepared monoclonal antibodies against the EDTA chelate of indium. These antibodies show a remarkable preference for indium chelates; changing to another metal such as scandium or gallium can decrease the antibody-binding constant by more than three orders of magnitude. These antibodies also introduce a new degree of control over the biological distributions of chelated radionuclides, markedly altering their uptake in tumours and normal organs.

Figure 1 shows the approximately 70 metallic elements that form stable EDTA chelates^{5,6}. These may possess properties such as radioactivity, luminescence or paramagnetism, leading to new molecular labels for use in nuclear medicine, immunoassay or magnetic resonance imaging^{2,3,7-10}. In solution, many of these chelates exist in dynamic equilibrium between several molecular configurations^{11,12}, but they can be crystallized as unique structures. Figure 2 shows a structure of iron(III)-EDTA; the EDTA chelates of indium(III), cadmium(II), cobalt(II) and manganese(II) crystallize in similar configurations¹³⁻¹⁷. Many other metal-EDTAs have different structures¹⁸⁻²³, thus, it is interesting to investigate whether an antibody against one metal-chelate can bind others in which the metal (or the chelator) is different.

To make antibodies against indium-EDTA, an antigen was prepared by conjugating L-SCN-C₆H₄-CH₂-EDTA to keyhole limpet haemocyanin using the methods of Meares *et al.*²⁴. After addition of indium(III), there was ~0.1 mg of attached chelate per mg of protein. To prepare antibody-producing hybridoma cell lines, spleen cells from BALB/c mice (multiply immunized with the antigen) were fused with a variant of the P3.653 myeloma cell line using the technique of Gerhard²⁵. The resulting hybridomas were screened by radioimmunoassay²⁶ for their ability to bind ¹¹¹In-L-NH₂-C₆H₄-CH₂-EDTA or ¹²⁵I-labelled bovine serum albumin bearing nonradioactive indium-EDTA groups; of 3,476 clones sampled, 102 produced antibodies possessing measurable affinity for the chelate. Based on their high titres and affinities, two IgG1 antibodies (from clones CHA255 and CHB235) were selected for further study. These monoclonal antibodies were purified from mouse ascites fluid

TABLE OF THE ELEMENTS																		VIIIA

Fig. 1 Metals that form stable EDTA chelates^{5,6}. Elements studied here are shown in bold face. A single underline indicates that the affinity of both antibodies for the metal-L-benzyl-EDTA chelate is 10–100 times less than for indium-L-benzyl-EDTA; a double underline 100–1,000 times less; a triple underline 1,000–10,000 times less.

by ion-exchange chromatography on DEAE-cellulose²⁷. Purity was routinely checked by SDS-polyacrylamide gel electrophoresis²⁸; for each purified sample, only one light-chain band and one heavy-chain band could be detected.

Binding constants for indium chelates were determined in triplicate by equilibrium dialysis and Scatchard analysis of a series of antibody-chelate solutions²⁹; as expected for IgG1, each antibody had 2 (± 0.2) binding sites for chelate. Indium-EDTA labelled with ¹¹¹In or ¹⁴C was used in parallel experiments (with similar results), confirming that each antibody binds the chelator as well as the metal. The binding constants for metal chelates other than In-L-benzyl-EDTA were determined by equilibrium dialysis in competition with ¹¹¹In-L-benzyl-EDTA; this procedure was validated by independent determinations of the binding constants of indium-[¹⁴C]EDTA and ⁵⁷Co-L-benzyl-EDTA, and also by isotope dilution using non-radioactive In-L-benzyl-EDTA. ¹¹¹In-L-benzyl-EDTA did not bind detectably (<0.1%) to normal whole mouse IgG or to mouse serum.

Metal chelates selected for testing (Fig. 1) included trivalent ions that are similar to indium (Sc, Ga, Fe), and divalent ions whose EDTA chelates can have structures similar to that of indium-EDTA (Mn, Co, Cd). Inspection of Table 1a shows that changing the metal in the chelate can decrease the antibody-binding constant K_b , by more than three orders of magnitude. The metals whose chelates bind best are indium(III), iron(III) and cadmium(II); the available crystal structures for their chelates are all similar to that in Fig. 2¹³⁻¹⁷. Table 1 also shows that the K_b values are not well correlated with either ionic radii or metal-chelate stability constants.

Each antibody is much like the other with regard to selectivity for metals (Fig. 1); however, the antibodies differ markedly in their sensitivity to changes in the chelator. Table 1b shows that CHB235 is almost unaffected by whether the side chain is in the D- or L-configuration (see Fig. 2), or whether there is a side chain at all. CHA255 is rather sensitive to the presence of the L-benzyl side chain.

Because metal ions have affinity for amino-acid side chains bearing sulphur, nitrogen or oxygen^{5,6}, antibodies are fundamentally well suited to binding metal ions or metal chelates. Some cancer patients have been found to produce myeloma proteins (antibodies) that bind copper or calcium ions^{30,31}, and certain heavy metals such as platinum can be immunogenic³²⁻³⁴. The methods used here can be applied to prepare antibodies against a variety of metal chelates. It is immediately clear that particular metal chelates—and therefore particular metal ions—can be selectively bound, analysed and manipulated by immunochemical techniques^{2,3,35}. This novel connection of immunochemistry to inorganic chemistry may find practical use; for example, in trace element analysis by immunoassay.

Table 1 Relative binding of metal chelates to monoclonal antibodies against an indium-EDTA analogue

a. Chelates of L-benzyl-EDTA with different metal ions				
Metals	r_{ion} (Å)	$\log K_s$ (EDTA)	K_b (CHA255)	K_b (CHB235)
Sc(III)	0.81	23.1	$3.0 \times 10^6 (\pm 13\%)$	$5 \times 10^4 (\pm 39\%)$
Fe(III)	0.64	25.1	$1.8 \times 10^8 (\pm 13\%)$	$2.4 \times 10^6 (\pm 18\%)$
Ga(III)	0.62	20.3	$5 \times 10^7 (\pm 45\%)$	$5.2 \times 10^5 (\pm 16\%)$
In(III)	0.81	25.0	$4.0 \times 10^9 (\pm 6.9\%)$	$1.1 \times 10^8 (\pm 7.9\%)$
Tb(III)	1.00	17.9	$1.2 \times 10^6 (\pm 12\%)$	$2.7 \times 10^4 (\pm 15\%)$
Yb(III)	0.94	19.5	$1.1 \times 10^6 (\pm 20\%)$	$2 \times 10^4 (\pm 90\%)$
Mn(II)	0.80	13.9	$2.8 \times 10^6 (\pm 9.1\%)$	$2.8 \times 10^4 (\pm 24\%)$
Co(II)	0.74	16.3	$2 \times 10^6 (\pm 37\%)$	$9.4 \times 10^5 (\pm 22\%)$
Co(III)	0.63	41.4	$8 \times 10^7 (\pm 60\%)$	$< 1 \times 10^4$
Cu(II)	0.69	18.8	$1.7 \times 10^6 (\pm 12\%)$	$8.1 \times 10^4 (\pm 11\%)$
Zn(II)	0.74	16.5	$1.4 \times 10^6 (\pm 14\%)$	$3.5 \times 10^4 (\pm 27\%)$
Cd(II)	0.97	16.5	$1.5 \times 10^7 (\pm 8.0\%)$	$1.6 \times 10^5 (\pm 8.1\%)$
b. Indium chelates with different chelators				
Chelators			K_b (CHA255)	K_b (CHB235)
L-Benzyl-EDTA			$4.0 \times 10^9 (\pm 6.9\%)$	$1.1 \times 10^8 (\pm 7.9\%)$
D-Benzyl-EDTA			$6 \times 10^7 (\pm 40\%)$	$3.6 \times 10^7 (\pm 9.3\%)$
EDTA			$1.7 \times 10^6 (\pm 8.3\%)$	$1.3 \times 10^6 (\pm 13\%)$
HED3A			$4.2 \times 10^7 (\pm 12\%)$	$4.0 \times 10^7 (\pm 14\%)$

a. Column 1, the metals whose L-benzyl-EDTA chelates (see Fig. 2) were tested against the indium chelate. Column 2, the ionic radius of each metal⁴⁰. Column 3, the logarithm of the stability constant^{5,6} for each metal-EDTA chelate at 25 °C. Columns 4 and 5, the antibody-binding constants of each metal-L-benzyl-EDTA chelate for the two different monoclonal antibodies studied (CHA255 and CHB235), in 0.05 M 2-hydroxyethyl piperazine ethane sulphonate, 0.1 M NaCl, 0.1% Na₂S₂O₄, 0.1% bovine serum albumin, pH 7.37 °C. Relative standard deviations are given in parentheses. For 'metal-free' Na⁺ L-benzyl-EDTA, K_b (CHA255) is $< 10^5$; in this case it is difficult to measure K_b accurately, as trace metal contaminants bind to the chelator. b. Column 1, the different chelators used to make indium chelates (see Fig. 2).

Fig. 2 Crystal structure of the Fe(III)-EDTA chelate, which is similar to those of In(III), Cd(II), Mn(II) and Co(II)¹³⁻¹⁷. EDTA supplies two nitrogen (N1, N2) and four oxygen (O1-O4) ligands to the metal (M), and a water molecule (OH₂) is also coordinated to the metal. For many of the experiments described here, a benzyl side chain (R = C₆H₅CH₂—) was attached to carbon-1, as indicated by the arrow (both the D- and L-configurations were studied). The chelator HED3A has an alcohol in place of one carboxylate group (for example, by replacement of oxygen-5 with two hydrogens). Drawing adapted from Hoard *et al.*¹⁴.

Fig. 3 Comparison of the distributions of radioactivity in BALB/c mice bearing KHJJ tumours³⁶, 24 h after injection of either 10 µg CHA255 anti-chelate antibody plus a trace of ¹¹¹In-L-benzyl-EDTA (a) or 100 µg CHA255 plus ¹¹¹In-L-benzyl-EDTA (b). Error bars represent 1 s.d. Note that the range of concentrations in b is 8.5 times that in a. Similar results were obtained with the CHB235 antibody, but larger amounts were required. When ¹¹¹In-L-benzyl-EDTA was injected without anti-chelate antibody, the concentrations of radioactivity were all less than 0.05% per g; this is insignificant on the scale of a.

These antibodies are also capable of altering the biological properties of metal chelates. For example, consider their effect on the behaviour of ¹¹¹In-L-benzyl-EDTA in BALB/c mice. Intravenous injection³⁶ of a trace of the radiochelate together with 10 µg of CHA255 per mouse increases the biological half-life of the chelate from 40 ± 15 min to 6 ± 1 h; when the amount of antibody is increased to 100 µg, the half-life increases to 54 ± 15 h. Nonspecific antibody, or quantities of specific antibody smaller than 1 µg per mouse, have no measurable effect on the biological behaviour of the indium chelate.

These 'reversibly radiolabelled' antibodies behave in a way that is qualitatively different from covalently radiolabelled antibodies. Figure 3 shows tumour and organ concentrations of radioactivity 24 h after injection of ¹¹¹In-L-benzyl-EDTA and anti-chelate antibody in mice bearing KHJJ tumours. By varying the antibody concentration *in vivo*, it is possible to enhance the uptake of radioactivity in the tumour relative to the rest of the body (Fig. 3a). All the radioactivity concentrations are strikingly increased in the presence of the antibody, with the tumour concentration rising from <0.05% per g up to 11.3% per g (Fig. 3b). Clearly, anti-chelate antibodies can introduce a new degree of control over the biological distribution of chelated radionuclides and other chelates used in medical diagnosis and therapy.

As the antibodies have no known affinity for the tumour, they are presumed to accumulate passively³⁷. Extension of the present work to prepare monoclonal antibodies with dual antigen specificity^{38,39}, which could simultaneously bind a metal chelate and a physiological antigen, may provide further improvements.

We thank R. Feeney, C. Schmid and J. Keizer for helpful discussions. This study was supported in part by grant CA16861 and RCDA CA00462 to C.F.M. and grant CA28343 to D.A.G. from the US National Cancer Institute, DHHS.

Factor IX (Christmas factor), a vitamin K-dependent plasma protein made in the liver, functions in the middle phase of the intrinsic pathway of blood coagulation¹. A functional deficiency of factor IX underlies haemophilia B, a chromosome X-linked recessive disease for which the major therapeutic approach is replacement treatment using factor IX concentrates. The cloning and characterization of the gene for human factor IX²⁻⁴ would mean that human factor IX could be produced in greater yield and purity through using recombinant DNA techniques⁵. We have now used a human factor IX cDNA clone⁴, inserted into a vaccinia virus-derived vector, to infect human hepatoma cells which normally produce no factor IX⁶, and mouse fibroblasts. Fully active factor IX was produced by the hepatoma cells, whereas the fibroblasts produced a protein less active than natural factor IX, even in the presence of high levels of vitamin K. Human factor IX is extensively post-translationally modified, and thus represents probably the most complex protein produced in active form by recombinant DNA techniques to date. Our study also illustrates the potential of vaccinia virus-based vectors for expressing significant amounts of complex, clinically useful proteins in eukaryotic cells, in addition to its already demonstrated usefulness for producing live recombinant vaccines⁷⁻⁹.

Factor IX is a protein of extraordinary complexity. Several sialic carbohydrates are linked to the protein chain and experiments have shown that these groups may be important for the activity of the molecule¹⁰. The first 12 glutamic acid residues of the mature enzyme are converted to γ -carboxyglutamic acids in a vitamin K-dependent process. These modifications are essential for the activation of factor IX. In addition, one aspartic acid residue (position 64) is hydroxylated¹¹⁻¹³, and may also be important for activation of the molecule^{11,12,14}.

Activation of factor IX from its zymogen form occurs through the action of activated factor XI. It involves two specific proteolytic cleavages, and releases an activation peptide, and the active proteolytic enzyme, factor IXa, whose two chains are held together by disulphide bridges. In addition, analysis of the factor IX gene sequence shows that the primary translation product of factor IX messenger RNA is a pre-pro form^{3,4}, though the zymogen precursor has not yet been characterized.

In a search for cells which can produce biologically active factor IX, we attempted to express the protein in several different cell lines. We first looked at a human hepatoma cell line, HepG2 (ref. 6), which synthesizes many different plasma proteins,

Fig. 1 Insertion of the factor IX cDNA coding sequence into vaccinia virus. The *Fnu*DII/*Pst*I fragment was isolated from the factor IX cDNA clone⁴, and the coding sequence at the 5' end together with a *Bam*HI site cohesive end were restored using a synthetic DNA linker. This fragment was then transferred to the plasmid pTGIH-tk-P7.5K (ref. 9) which contains the vaccinia virus *tk* gene insertionally inactivated by the presence of the early 7.5K promoter of vaccinia virus. The resulting plasmid, pTG393, contains the factor IX cDNA sequence immediately adjacent to the 7.5K promoter, and flanked on either side by parts of the vaccinia *tk* gene. These flanking regions allowed the *in vivo* recombination of the factor IX sequence of pTG393, together with the 7.5K promoter, into the N7 strain of vaccinia virus (derived from the Copenhagen strain) using procedures already described⁹. The fine dotted regions represent the factor IX cDNA sequence, the larger dotted regions the vaccinia *tk* gene, and the black area the 7.5K promoter.

including factor X and protein C, which are closely related to factor IX and undergo many of the same modifications. However, no factor IX synthesis was found in these cells⁶, nor have we been able to detect significant levels of factor IX mRNA in the cells (unpublished observations).

To express factor IX in HepG2 cells, we used vaccinia virus as a vector. The strategy for insertion of a gene into the vaccinia genome has been described previously⁷⁻⁹ and is based on a homologous recombination between the thymidine kinase (TK) gene in the viral genome and the plasmid bearing the gene to be expressed, generating a TK⁻ recombinant virus (Fig. 1). One such TK⁻ virus was analysed by Southern blotting to verify that the pattern of restriction fragments of the cDNA inserted in the vaccinia genome was the same as in the starting plasmid (Fig. 2).

To establish whether the inserted factor IX gene was expressed during vaccinia infection, HepG2 cells infected for 15 h were labelled for 5 h with ³⁵S-methionine. Both cell extracts and culture medium were immunoprecipitated with IgGs prepared from rabbit anti-human factor IX antiserum. Two relatively diffuse bands, of apparent relative molecular masses (*M*_s) 79,000 (79K) and 71K, were specifically immunoprecipitated from the medium of HepG2 cells infected with the factor IX recombinant vaccinia virus (Fig. 3A, lane 2) but were absent from cells infected with wild-type virus (lane 1) or from media precipitated with non-immune serum (lanes 5-8). The smaller of the specifically immunoprecipitated bands has an apparent

Fig. 2 Verification of the insertion of the factor IX cDNA sequence into vaccinia virus. **A**, Ethidium bromide-stained gel before transfer. Lane *a*, M_r standards from a digest of λ DNA with *EcoRI* and *HindIII*; lane *b*, a mixture of different digests of the plasmid, pTG393, carrying the factor IX sequence within the vaccinia *tk* gene. A different digest, with *PstI* alone, *PstI* + *HindIII*, *PstI* + *AvaI* and *PstI* + *AvaII* were mixed before electrophoresis. The fragments which should contain factor IX sequences are marked by arrows, and have sizes of 9.0, 3.0, 2.11, 1.45 and 0.85 kilobases, respectively. Lane 1, mixture of pTG393 digests as for lane *b*, but with 10 ng of DNA instead of 1.0 μ g; lanes 2–5, DNA of infected cells digested with *PstI* (lane 2), *PstI* + *HindIII* (3), *PstI* + *AvaI* (4), *PstI* + *AvaII* (5). **B**, Autoradiogram of nitrocellulose filter hybridized with ^{32} P-labelled factor IX probe. Lanes 1–5 correspond to the same lanes as for **A**. The two largest bands in lanes 4 and 5 (arrows on right) correspond to end fragments of the factor IX portion of pTG393 flanked by vaccinia sequence, and so do not correspond in size to the hybridizing fragments of pTG393 alone (lane 1).

Methods. A 75-cm² flask of confluent chick embryo primary fibroblast cells was infected with 0.5 plaque-forming units per cell of recombinant vaccinia virus. After 2 days, cells were collected, lysed and DNA was prepared by standard procedures. The DNA was digested with various restriction enzymes, electrophoresed on a 1% agarose gel and blotted onto nitrocellulose. The filter was hybridized with ^{32} P-labelled factor cDNA probe.

size consistent with that of natural factor IX; the other may represent a precursor form of factor IX, or perhaps a molecule containing a different form of glycosylation.

The analysis of supernatants from HepG2 cells infected and labelled in the presence of tunicamycin, an inhibitor of *N*-glycosylation, revealed several specific bands of greater mobility from cells infected with the recombinant vaccinia virus (Fig. 3A, lane 3). Moreover, the ability of unlabelled factor IX to compete with the medium polypeptides (Fig. 3B, lanes 1, 3) provided additional evidence that the immunoprecipitated polypeptides were factor IX molecules.

To characterize further recombinant factor IX produced by the vaccinia vector, and to determine whether the product exhibited biological activity, medium from infected cells was fractionated using barium citrate¹⁵. This fractionation is based on the ability of γ -carboxylated proteins to adsorb to the insoluble salt of barium citrate¹⁵. Fully γ -carboxylated molecules co-precipitate with the salt, while non-carboxylated molecules stay in solution. The properties of a partially modified protein are not known in the case of factor IX, but studies with prothrombin, another γ -carboxylated protein, have shown that the extent of precipitation is related to the number of γ -carboxyglutamic acid residues present¹⁵. We used a commercially available enzyme-linked immunosorbent assay to quantitate factor IX antigen through the fractionation procedure, and the activity of barium citrate-adsorbed fractions was measured as their ability to restore coagulability to plasma congenitally deficient in factor IX¹⁶. Both factor IX antigen and activity are expressed in arbitrary units; 1 unit corresponds to the quantity of factor IX in 1 ml of normal human pooled plasma ($\sim 5 \mu$ g).

Fig. 3 Immunoprecipitation of recombinant human factor IX. **A**, Immunoprecipitates with labelled cell media. Lane 1, medium from cells infected with wild-type virus; lane 2, medium of cells infected with recombinant virus; lane 3, as for lane 2, but cells grown in tunicamycin; lane 4, as for lane 1, but cells grown in the presence of tunicamycin; lanes 5–8, as for lanes 1–4, but non-immune IgG used instead of anti-factor IX IgG. Numbers on the left represent M_r markers ($\times 10^{-3}$). **B**, Immunoprecipitation with native factor IX. Competitions were performed by adding 10 μ g of natural human factor IX to cell media or extracts before IgG addition. Lane 1, medium from cells precipitated in the presence of competitor; lane 2, as for lane 1, but without competitor; lane 3, medium from tunicamycin-treated cells precipitated in the presence of competitor; lane 4, as for lane 3, but without competitor.

Methods. Confluent hepatoma cells were infected with either recombinant or wild-type vaccinia virus, either in the presence or absence of 1μ g ml⁻¹ tunicamycin. After 24 h of infection, the medium was removed and replaced by a synthetic medium lacking cold methionine. ^{35} S-methionine (specific activity ≥ 800 Ci mmol⁻¹) was added at 50μ Ci ml⁻¹, and labelling was carried out for 5 h to obtain labelled supernatants. For cells pretreated with tunicamycin, the compound was also present at 1μ g ml⁻¹ in the labelling medium. Cells and media were collected, the cells were lysed in 1% Triton X-100 and aliquots of the medium (10^5 c.p.m. of trichloroacetic acid-precipitable radioactivity) were subjected to immunoprecipitation¹⁷ with rabbit anti-human factor IX IgG or non-immune rabbit IgG. The immunoprecipitates were analysed by 7.5% polyacrylamide gel electrophoresis¹⁸, followed by fluorography and autoradiography.

We infected both HepG2 and the mouse fibroblast LM-TK⁻ cell lines with either the wild type or the recombinant vaccinia virus and analysed the medium at several times after absorption of the virus (Table 1a). Although the factor IX complementary DNA is under the control of the early 7.5K promoter, in the recombinant vaccinia virus construct, we obtained maximal expression of both antigen and activity after ~ 22 h of infection. In fact, the 7.5K promoter is known to be expressed during the entire viral cycle, so the high levels of late expression probably appear after the replication of the viral genome. In medium from cells infected with wild-type vaccinia virus, no significant levels of either factor IX antigen or activity were observed. It is also significant that although there is a good correlation between antigen and activity in the barium citrate-adsorbed fraction for HepG2 cells, this is not the case for the LM-TK⁻ cells (see below). The differences in absolute levels of factor IX produced probably do not result from differences in expression in the two different cell lines, but rather correlate with the

a, HepG2 and LM-TK⁻ cells were grown to confluence on 75-cm² plates (~2 and 1 × 10⁷ cells, respectively), then infected with the recombinant factor IX-containing vaccinia virus. These infections were performed in modified Eagle's (MEM) medium supplemented with 10% fetal calf serum (FCS) and 50 µg ml⁻¹ vitamin K. The medium was removed at various times after infection, fractionated using barium citrate as described in the text, and factor IX antigen and activity were measured. b, HepG2 cells were passaged five times in MEM supplemented with 2% serum substitute Ultrosor G (IBF) to lower endogenous vitamin K levels of the cells. Then confluent monolayers in the same medium were infected with the recombinant vaccinia virus, either in the presence or absence of 50 µg ml⁻¹ vitamin K. For the LM-TK⁻ cells, confluent monolayers grown in MEM + 10% FCS were infected in the presence or absence of added vitamin K (50 µg ml⁻¹). Cell media were fractionated, and factor IX antigen and activity were measured as above. For these experiments vitamin K was dissolved in ethanol (50 mg ml⁻¹), then added to the medium. The results are expressed in units, 1 unit corresponding to the quantity of factor IX in 1 ml of normal human pooled plasma. w.t., Wild-type N7 Copenhagen vaccinia virus; rec., recombinant virus; ND, not determined.

number of cells used. Subsequent experiments were performed using medium from cells infected for ~24 h.

As γ-carboxylation of the glutamic acid residues of factor IX is vitamin K-dependent, we investigated the effect of vitamin K on the production of recombinant factor IX (Table 1b). Vitamin K had no effect on the total production of factor IX by HepG2 cells infected with vaccinia, in contrast to the vitamin K-dependent stimulation of prothrombin synthesis reported for this cell line⁶. However, the vitamin did have a marked effect on the distribution of factor IX between the two fractions produced by barium citrate fractionation. When vitamin K was not added, a large part of the synthesized factor IX did not adsorb to barium citrate, but when it was present most of the factor IX bound to the salt.

The factor IX molecules produced by infected HepG2 cells were fully active if vitamin K was present in excess in the medium, but when it was absent the specific activity of factor IX adsorbed to barium citrate was halved. We propose that partially carboxylated proteins can bind to the barium salt, but exhibit a lower biological activity. Similar results were obtained with LM-TK⁻-infected cells, but a striking difference was seen between the factor IX produced by these cells and that from HepG2 cells. Even with an excess of vitamin K in the medium, the molecules produced by infected LM-TK⁻ cells and adsorbed to barium citrate appeared to be three times less active than natural factor IX. As we also found a significant amount of factor IX antigen in the non-adsorbed fraction, we consider that the γ-carboxylation must be less efficient in this cell line. This would explain why the factor produced by LM-TK⁻ cells, even in the presence of vitamin K, was not fully active.

We have demonstrated here the feasibility of producing biologically active factor IX in mammalian cells. The concentration

of factor IX activity in supernatants of infected cells is less than that present in pooled human plasma, but this represents a first step towards the production of a highly purified recombinant protein that could be used to treat haemophilia B.

We thank Professors Pierre Chambon and Philippe Kourilsky for their continued interest in this work, Drs T. Edgington, D. Fair, D. Meyer, J.-M. Freyssinet, M.-L. Wiesel and L. Grunebaum for many helpful discussions, the Wistar Institute for providing the HepG2 cell line, D. Fair for anti-factor IX antibodies, Drs M.-L. Wiesel and L. Grunebaum for biological assays, and Irène Batra for secretarial assistance. This project is supported by Institut Mérieux, Lyon.

Factor IX is the precursor of a serine protease that functions in the intrinsic blood clotting pathway¹. Deficiencies in this plasma glycoprotein result in haemophilia B (or Christmas disease) and occur in about 1 in 30,000 males². Patients are currently treated with fresh frozen plasma or prothrombin complex concentrates prepared from pooled plasma from normal individuals. There are several problems with this method of treatment, including the probable exposure of the patients to contaminants such as the viral agents responsible for hepatitis and AIDS (acquired immune deficiency syndrome). As a first step towards an alternative source of pure human factor IX, we report here on the use of recombinant DNA techniques to produce biologically active factor IX in cultured mammalian cells. Stable cell lines were produced by co-transfecting a baby hamster kidney (BHK) cell line with a plasmid containing a gene for factor IX and a plasmid containing a selectable marker. Protein secreted by these cell lines reduces the clotting time of plasma from factor IX-deficient patients. We present additional evidence that this protein is authentic human factor IX.

We report here the expression of an active vitamin K-dependent protein using recombinant DNA techniques. Factor IX is one of six identified plasma proteins whose biosynthesis is dependent on this vitamin^{1,3}. Vitamin K is a cofactor of the microsomal enzymes that perform post-translational modifications to produce the γ -carboxyglutamic acid (gla) residues characteristic of these proteins. The gla residues, which bind Ca^{2+} and allow the protein to interact with phospholipid, are necessary for biological activity⁴.

Human factor IX circulates in the blood as a single-chain glycoprotein of M_r 57,000 (ref. 1). During blood coagulation, it is converted to an active serine protease (factor IXa) after cleavage by factor XIa. Factor IXa, which consists of a light chain and a heavy chain (M_r 16,000 and 29,000, respectively) held together by a disulphide bond(s), then converts factor X to factor Xa in the presence of factor VIIIa, phospholipid and Ca^{2+} (ref. 1).

To express factor IX in cultured cells, we used a complementary DNA⁵ containing 138 base pairs (bp) that encode the 46-amino-acid leader, 1,248 bp that encode the 415-amino-acid mature protein and 48 bp of 3' noncoding DNA sequence. As described in Fig. 1 legend, this cDNA was inserted into a plasmid containing the adenovirus-2 major late promoter, a set of RNA splice sites and the simian virus 40 (SV40) polyadenylation signal. BHK cells were co-transfected with the factor IX plasmid (FIX/pD2) and pKOneo, a plasmid containing the gene for resistance to the antibiotic G418 (ref. 6). G418-resistant colonies were isolated and screened for the presence of factor IX activity secreted into the media; ~50% of the resistant colonies analysed secreted detectable factor IX activity. In subsequent analyses of a representative clone (IX-F), the supernatant media and the cell pellets of clone IX-F were assayed for the amounts of biologically active factor IX and factor IX polypeptide. The assay for biological activity was based on the ability of the sample to reduce the blood clotting time of plasma from factor IX-deficient patients⁷ and the amount of factor IX polypeptide was determined by an enzyme-linked immunosorbent assay (ELISA) using an affinity-purified polyclonal rabbit antibody to factor IX. The cells were grown for different lengths of time, and the media and cells collected for analysis. Most of the factor

Cells from clone IX-F were plated at 1.5×10^5 cells per 10-cm dish in Dulbecco's modified Eagle's medium containing 10% fetal calf serum and $1 \mu\text{g ml}^{-1}$ vitamin K (phytonadione, Merck). At the indicated time, the medium was aspirated, centrifuged at 2,000 r.p.m. for 10 min and frozen at -80°C . The cells were trypsinized, washed twice with Dulbecco's medium and counted. The cell pellet was frozen at -80°C . For the protein assays, the supernatant samples were thawed and assayed for biological activity by a one-stage clotting assay. This assay is based on the ability of the sample to decrease the prolonged activated partial thromboplastin time of congenital factor IX-deficient plasma. Normal control plasma (0.1 ml) (George King Biomedical Co.) or supernatant medium (0.1 ml) was incubated with factor IX-deficient plasma (0.1 ml) (George King Biomedical Co.) and cephaline-kaolin mixture⁷ (0.1 ml) for 12 min at 37°C . Then 40 mM CaCl_2 (0.1 ml) was added and the clotting time recorded. The factor IX activity was expressed as a percentage of the activity present in normal plasma and then converted to ng ml⁻¹ using a standard value of $3 \mu\text{g ml}^{-1}$ of factor IX in normal plasma. The cell pellets were extracted by freeze-thawing three times in 2 ml phosphate-buffered saline (PBS) and then centrifuged for 5 min in a microfuge. The pellet was re-extracted in 1 ml PBS, 0.25% Triton X-100. The samples were diluted 1:5 for ELISA. The amount of factor IX polypeptide present in the samples was measured by ELISA as follows. Affinity-purified rabbit polyclonal antibody against human factor IX ($200 \mu\text{l}$ of $1 \mu\text{g ml}^{-1}$ in 0.1 M Na_2CO_3 , pH 9.6) was incubated in each well of 96-well microtitre plates overnight at 4°C or for 2 h at 37°C . The wells were washed three times with PBS, 0.05% Tween 20 and then incubated with $220 \mu\text{l}$ of 1% bovine serum albumin (BSA), 0.05% Tween 20 in PBS, pH 7.2 overnight at 4°C or for 2 h at 37°C . The plates were rinsed several times in distilled water, air-dried and stored at 4°C . To assay samples containing factor IX, $200 \mu\text{l}$ of each sample was incubated for 1 h at room temperature in the antibody-coated wells. The wells were rinsed four times with 0.05% Tween 20 in PBS and then incubated for 1 h at room temperature with affinity-purified rabbit polyclonal anti-factor IX conjugated to alkaline phosphatase in PBS containing 1% BSA and 0.05% Tween 20. The per cent active protein was calculated by dividing the amount of factor IX activity in the medium by the amount of factor IX polypeptide in the medium. The same analyses were performed on spent media and cell pellets from control BHK cells and no factor IX was detected. To produce clone IX-F, the plasmid FIX/pD2 was introduced into BHK cells by calcium phosphate-mediated transfection¹¹. To transfect one 100-mm dish of 20% confluent cells, a total of $20 \mu\text{g}$ DNA was used: $5 \mu\text{g}$ of FIX/pD2, $5 \mu\text{g}$ pKOneo and $10 \mu\text{g}$ salmon sperm DNA. Twenty-four hours after transfection, selective medium (0.5 mg ml^{-1} , Gibco G418) was added. Resistant colonies were picked after 10–13 days. ND, not detectable.

IX polypeptide (70–80%) was secreted into the media, and ~50% of the secreted protein was biologically active (Table 1). No biological activity was detected in the cellular extracts despite the presence of factor IX polypeptide. Extracts of BHK cells had no inhibitory effect on the clotting assay.

It was necessary to supplement the cell culture medium with vitamin K at $1\text{--}10 \mu\text{g ml}^{-1}$ to detect factor IX clotting activity (data not shown). In the absence of vitamin K, the cells secreted factor IX polypeptide at somewhat higher levels than when vitamin K was present. However, without vitamin K, little or no factor IX clotting activity was detected.

Additional analyses were performed to demonstrate that these cells were secreting factor IX. Samples containing factor IX activity as measured by the above assay were incubated with factor VIII-deficient plasma; none of these samples shortened the clotting times of factor VIII-deficient plasma (data not shown). Therefore, it seemed that the activity was due to factor IX rather than an artefactual agent. This conclusion was confirmed by the finding that treatment of the samples with an affinity-purified rabbit polyclonal antibody against human

Fig. 1 Diagram of the factor IX construction used in our experiments. The factor IX cDNA obtained by Kurachi and Davie⁵ begins with the first methionine (ATG) of the protein leader sequence¹². The sequence of the 5' end was altered from CTGCAGG₁₁ ATG to CTGCAGGATCCATG to remove the G₁₁ and to introduce a *Bam*HI site 5' of the ATG. An adaptor was made by annealing two synthetic single-stranded DNAs, filling-in with T4 polymerase, and then digesting with the restriction enzymes *Pst*I and *Cfo*I. The resulting 19-bp *Pst*I/*Cfo*I fragment was ligated with a 1.4-kb *Cfo*I/*Bam*HI fragment which contained the remainder of the factor IX cDNA and a 2.7-kb *Bam*HI/*Pst*I fragment of pUC13. The DNA construction was confirmed by sequencing through the region where the adaptor was inserted. The cDNA was then isolated as a *Bam*HI fragment and inserted into the *Bam*HI site in the vector pD2 to make FIX/pD2. The pD2 plasmid (5.3 kb) was derived from plasmid pDHFR-III (ref. 13) and contains the adenovirus-2 major late promoter (MLP), the cDNA encoding the entire tripartite leader (L), a splice set (SS) composed of the adenovirus-2 third leader 5' splice site and an immunoglobulin 3' splice site, and the early SV40 polyadenylation signal (pA). R, *Eco*RI restriction enzyme site; B, *Bam*HI site.

factor IX removed 98% of the factor IX activity. This antibody also precipitated 99% of the factor IX activity from normal plasma. When the samples were immunoprecipitated with a rabbit polyclonal antibody to human erythropoietin, none of the factor IX activity was removed from the samples.

Barium citrate has been used to adsorb selectively proteins containing gla residues⁸. Culture medium from cell line IX-F was subjected to adsorption as described in Table 2 legend. The supernatant and the pellet fractions were assayed by the clotting assay and by ELISA. The ELISA data (Table 2) show that while 50% of the factor IX polypeptide was adsorbed to barium citrate, almost all of the biologically active factor IX was properly carboxylated (and therefore adsorbed to barium citrate), whereas the inactive factor IX was probably deficient in gla residues. Human factor IX isolated from plasma contains 12 gla residues⁹. Protein sequence and amino-acid composition analyses of our active and inactive factor IX fraction will be necessary to determine precisely the extent of carboxylation in the factor IX produced by BHK cells.

A Western blot analysis was performed on the material adsorbed to barium citrate from spent media of cell line IX-F and BHK cells, and from normal plasma. The protein secreted by IX-F (Fig. 2, lane 2) migrated with the same apparent M_r as the single-chain form of factor IX in normal plasma (lane 3) and of purified factor IX (lane 4). These results indicate that the cells secreted human factor IX of the correct size and that the single-chain form was stable in the cell culture medium for up to 6 days.

The present work demonstrates that biologically active human factor IX can be produced in BHK cells. Additional studies are in progress to increase the levels of protein secretion and to optimize the expression of active factor IX in transfected cells. Since variation has been observed in the rate of carboxylation by microsomal fractions from different tissues¹⁰, one parameter

Fig. 2 Western blot of factor IX adsorbed to barium citrate. Spent media were collected from BHK cells and from IX-F cells grown for 6 days as described previously. Aliquots (2 ml) of each medium sample and normal plasma (2 ml) were adjusted to 23.8 mM sodium citrate and incubated at 4 °C for 5 min. Barium chloride was added to a final concentration of 45.5 mM, incubated at 4 °C for 30 min and centrifuged at 3,000 r.p.m. for 2 min. The pellets were washed twice with PBS and redissolved in 2 ml of PBS containing 0.15 M sodium citrate. The IX-F sample contained 400 ng ml⁻¹ factor IX by ELISA, and the control BHK samples contained none. The samples were dialysed for 4 h at 4 °C against PBS and then concentrated using Aquacide III (Calbiochem-Behring) to a volume of 300 μ l. The control BHK sample (lane 1), the IX-F sample (75 μ l; 75 ng of factor IX) (lane 2), normal plasma (20 μ l; 400 ng of factor IX) (lane 3) and PBS (50 μ l) containing 1 μ g of purified factor IX (lane 4) were subjected to electrophoresis in a 10% polyacrylamide gel (acryl:bis, 3.75:1). After the proteins had been transferred to nitrocellulose, the filter was washed with transfer buffer A (50 mM Tris-HCl pH 7.4, 5 mM EDTA, 50 mM NaCl, 0.25% (w/w) gelatin, 0.05% NP40) and incubated with rabbit polyclonal antibody to factor IX for 1 h at room temperature. After three more 15-min washes with buffer A, the filter was incubated with goat anti-rabbit IgG conjugated with horseradish peroxidase (HRP) for 1 h at room temperature, washed once with distilled H₂O, twice with buffer B (same as buffer A but also containing 0.4% N-lauryl sarcosine sodium salt) for 15 min, and finally incubated with HRP colour reagent (Bio-Rad). The factor IX in all lanes migrated with an apparent M_r of 66,000. Presumably this difference from the reported 57,000 M_r results from the electrophoretic properties of factor IX in this system. Some degradation of the purified factor IX standard (lane 4) was apparent. The M_r standards (BRL, pre-stained with Coomassie blue) (lane M) are myosin heavy chain (200,000 or 200K), phosphorylase b (92,500), BSA (68,000), ovalbumin (43,000) and α -chymotrypsin (25,700).

Table 2 Barium citrate adsorption of factor IX from cell culture medium

Sample	Factor IX (ng) (ELISA)	Factor IX (ng) (activity)
Medium from clone IX-F	5,288	3,186
Supernatant fraction after precipitation and dialysis	2,641	14
Redissolved precipitate	1,500	1,935

Spent media were collected from cell line IX-F and assayed by ELISA and by the clotting assay. A 4.8-ml aliquot of medium was adjusted to 20 mM sodium citrate and the sample was incubated for 5 min at 4 °C. Barium chloride was added to a final concentration of 40 mM and the sample was incubated at 4 °C for 30 min and then centrifuged at 3,000 r.p.m. for 2 min. The supernatant was dialysed against PBS at 4 °C, and then assayed. The pellet of insoluble barium citrate was redissolved in PBS containing 0.1% BSA and 0.15 M sodium citrate, dialysed against PBS and then assayed. According to both the activity assay and the ELISA, the per cent recovery of protein from the barium citrate pellet in this experiment was about 60%. We found that the per cent recovery varied between experiments, but the activity and the ELISA measurements were always consistent. Spent media collected from control BHK cells were subjected to the same analysis, and no factor IX activity or ELISA-positive material was detected.

to explore is the efficiency of γ -carboxylation in other cultured cell lines. From these initial studies, however, it is clear that this approach provides the basis for establishing an abundant pure source of human factor IX.

We thank Charles Hart, Patrick O'Hara, Teresa Gilbert and Donna Prunkard for their contributions and Kazuo Fujikawa for the purified human factor IX. K.K. was supported by NIH grant HL31511.

Isolation of a new human oncogene from a diffuse B-cell lymphoma

Alessandra Eva & Stuart A. Aaronson

Laboratory of Cellular and Molecular Biology,
National Cancer Institute, Bethesda, Maryland 20205, USA

Utilizing DNA transfection analysis¹ with the continuous NIH 3T3 cell line as assay cell², we³ and others^{4,5} have observed that as many as 10-50% of human haematopoietic tumours contain oncogenes, the vast majority of which are members of the *ras* proto-oncogene family. In addition, Cooper and co-workers⁶⁻⁸ have reported the detection and isolation of specific oncogenes, *B-lym* and *T-lym*, which appear to be activated in human and rodent tumours of certain B and T lymphoid cells, respectively. In surveying human haematopoietic malignancies, we observed that DNA of a primary human diffuse B-cell lymphoma induced an unusual transformed focus on transfection of NIH 3T3 cells. Here, we report the molecular cloning and physical characterization of this human oncogene, whose transforming activity was shown to reside within a human DNA sequence of 45 kilobases (kb) cloned in a cosmid vector. Its properties distinguish it from previously reported retroviral or nonretroviral oncogenes.

High relative molecular mass (M_r) DNA was isolated from the affected spleen of a patient with diffuse B-cell lymphoma. When the DNA was tested in the NIH 3T3 transfection assay, transforming activity was observed at low efficiency. The transformed cells demonstrated a very distinct phenotype (Fig. 1). At least three types of morphologically distinguishable cells were visible: giant polynucleated cells, densely growing fibroblast-like cells and very refractile and round cells (Fig. 1). The unusual phenotype of the transformed focus appeared to be a genetically stable property. Clonally derived lines retained the complex morphology of the originally observed transformed focus.

A first-cycle focus was picked and the transformant grown up to mass culture. DNA of the primary transfectant was shown to contain human repetitive sequences, indicating that the transfectant had incorporated exogenous human DNA. Transmissibility of the transformed phenotype was retained in subsequent cycles of transfection with concomitant increased efficiency (Table 1). Moreover, cell lines established from first-, second- and third-cycle transfectants induced by this human transform-

Fig. 1 Morphology of a transformed focus induced in NIH 3T3 cells by transfection of high- M_r DNA from a human diffuse B-cell lymphoma. *a*, $\times 140$; *b*, $\times 360$.

ing gene possessed known properties of malignant cells (Table 1).

We then analysed second- and third-cycle transfectants by Southern blotting analysis and hybridization with a probe specific for human repetitive sequences. As shown in Fig. 2, human sequences were detected in each transfectant analysed. The pattern of human DNA fragments observed following digestion with different enzymes indicated the retention of specific human fragments through several cycles of transfection, implying their probable association with the transforming gene.

Most human transforming genes detected by transfection analysis to date have been found to be members of the *ras* family, with *N-ras* the most frequently activated oncogene in human haematopoietic tumours³⁻⁵. To exclude the possibility that the newly detected oncogene was related to any of the known *ras* genes, we analysed transfectant DNAs by Southern blotting for the presence of human *ras*-related sequences. None of the *ras* gene probes detected related sequences other than those normally present in mouse cells (data not shown).

A third-cycle transfectant DNA was partially digested with *EcoRI*, selected by sucrose gradient for the size range of 35-45 kb and cloned into cosmid pH79. A library of 300,000 recombinants was screened with human genomic DNA as a probe. Four overlapping clones were isolated (C14-1-2, C5-1-1, C44-1-6, and C8X-1-1, Fig. 3a), whose 40-45-kb inserts contained human repetitive sequences. A preliminary restriction map was constructed and is shown in Fig. 3b. *EcoRI* and *HindIII*, which cut each of the inserts a minimum of nine times, were partially mapped, so only those *EcoRI* and *HindIII* sites that were

Fig. 2 Detection of human sequences in NIH 3T3 cells transformed by DNA of a diffuse B-cell lymphoma. High M_r DNA (20 μ g) was digested with *Eco*RI (a), *Bam*HI (b) or *Hind*III (c), electrophoresed, blotted and hybridized to ^{32} P-labelled nick-translated 0.3-kb cloned repetitive sequence DNA fragment purified from plasmid BLUR-8 (2×10^6 c.p.m. ml^{-1}). Cellular DNA was isolated from one representative second-cycle transfectant (lanes 1, 4, 7) and two representative third-cycle transfectants (lanes 2, 5, 8 and 3, 6, 9, respectively). *Hind*III fragments of λ DNA served as M_r standards.

determined are indicated. As shown in Fig. 3c, two of the clones, C5-1-1 and C14-1-2, contained only human sequences and were placed in the map arbitrarily at the left end of the cloned DNA sequences. The other two clones, C44-1-6 and C8X-1-1, contained both human and mouse repetitive sequences and thus probably represented one of the junctions of the human acquired sequence with mouse DNA.

To establish whether any of the clones possessed transforming activity, we transfected NIH 3T3 cells with varying amounts of each of the recombinant cosmid DNAs. C14-1-2, which contained a 45-kb human DNA fragment, was found to be biologically active in three separate experiments using two different DNA preparations with an efficiency of focus formation of about 600 focus forming units per pmol (data not shown). The morphology of transformed foci induced by the cloned oncogene was indistinguishable from that observed by transfecting NIH 3T3 with the original human tumour or transfectant DNAs.

DNAs of representative foci obtained by transfection with C14-1-2 DNA were analysed by Southern blotting using as probes a 4.5-kb *Bam*HI fragment that maps at the right end of C14-1-2 (Fig. 3a). We found that this probe recognized DNA fragments of the sizes expected from the physical map of C14-1-2 in all the transfectant DNAs analysed. All of these findings established that the C14-1-2 recombinant cosmid clone contained the biologically active transforming gene.

We hybridized third-cycle transfectant DNAs with cloned viral and cellular oncogenes and performed reciprocal hybridization studies between these probes and the cloned oncogene. In addition to its lack of homology with any of the known *ras* genes, the transforming gene lacked detectable relationship to *sis*, *rel*, *fos*, *erb-B*, *B-lym*, *N-myc*, *fgr*, *fes*, *src*, *ets*, *fms*, *p53*, *myb*, *mos*, *abl*, *myc* and *raf* (data not shown). Furthermore, its restriction map was different from that of *T-lym*⁸ as well as that recently reported for *met*⁹. Finally, comparison of the pattern of *Alu*-containing fragments of second- and third-cycle transfectants with the human specific fragments of *met*⁹, *mcf-2*¹⁰, *mcf-3*¹⁰,

Fig. 3 Restriction map of *dbl*. a, Genomic DNA of a third-cycle transfectant was partially digested with *Eco*RI to select for fragments of from 35–45 kb and cloned in pHC79 cosmid cloning vector. The library was screened without amplification with ^{32} P-labelled nick-translated, sheared human genomic DNA as a probe. The four overlapping recombinant clones obtained are indicated. A *Bam*HI restriction fragment of cosmid clone C14-1-2 was subcloned in pAT153 (subclone pB 4.5). b, Restriction map of the cloned cellular DNA. *Hind*III and *Eco*RI were only partially mapped. c, Human (open box) and mouse (hatched box) specific sequences were determined by hybridization with ^{32} P-labelled nick-translated, human genomic DNA, human *Alu* clone BLUR-8 and mouse genomic DNA.

NK14¹¹ and *neu* oncogenes¹² indicated a lack of homology between our transforming gene and any of these recently detected oncogenes.

Our present studies provide the first report of a transforming gene associated with a human diffuse B-cell lymphoma. This newly identified oncogene, which we designate *dbl* for diffuse B-cell lymphoma, conferred the transformed phenotype on NIH 3T3 cells, inducing an unusual focus composed of small and spindle-shaped refractile cells as well as large multinucleated giant cells. Despite the low transforming activity of the original human tumour DNA, we presume that the transforming gene arose from within the tumour, as we have not observed transformed foci induced by normal human DNA in a large series of transfection experiments. However, direct confirmation must await further characterization of the structure of the oncogene as it resides within the tumour. The distinct phenotype

Table 1 Transforming properties of DNA from a human diffuse B-cell lymphoma

Transforming activity		Properties of transformed cells		
Donor DNA	No. foci per plate*	Saturation density (cells $\times 10^{-5}$ per cm^2)†	% Colony formation in agar‡	Tumour incidence§
I cycle	0.12	2.0-3.0	5-10	5/5
II cycle	1.5	2.0-3.0	5-10	5/5
III cycle	3.0	2.0-3.0	5-10	5/5
Control NIH 3T3	<0.03	1.0	<0.01	0/5

* 1.5×10^5 NIH 3T3 were transfected with 40 μ g of high M_r DNA by the calcium phosphate method¹. Results represent mean values of at least eight recipient cultures.

† The maximum cell number obtained when 5×10^3 cells per cm^2 were inoculated onto 20-cm² Petri dishes in conditions where the medium containing 5% calf serum was changed every 3 days. Saturation density was taken as that value where successive cell counts at 2-day intervals showed no increase in cell number.

‡ Cell suspensions were plated at 10-fold serial dilutions in 0.33% soft agar medium containing 10% calf serum. Visible colonies comprising >100 cells were scored at 14 days.

§ NFR nude mice were inoculated subcutaneously with 1×10^5 cells of each cell line. Tumour formation was monitored for up to 30 days.

of transformants induced by this oncogene suggests that the NIH 3T3 transfection assay may reveal other oncogenes which induce alterations that differ from those caused by *ras* oncogenes.

Our isolation of a 45-kb cosmid clone comprised of human sequences, which induced transformation on DNA transfection, demonstrates that the transforming gene was obtained in a biologically intact form. This clone was only one of four isolated by cosmid cloning of *Eco*RI partially digested genomic DNA. Thus, it is likely that restriction sites outside the transforming region were preferentially cleaved by the cloning enzyme. To our knowledge this 45-kb DNA sequence represents the largest biologically active transforming DNA so far isolated.

We thank R. Trimmer for technical assistance, and S. R. Tronick, V. Notario and G. Vecchio for helpful advice and discussion. We also acknowledge the assistance of F. Chieco-Bianchi in the early stages of this study.

Control of transcription of α -amylase and rRNA genes in barley aleurone protoplasts by gibberellin and abscisic acid

J. V. Jacobsen & L. R. Beach*

Division of Plant Industry, CSIRO, PO Box 1600, Canberra, ACT 2601, Australia

Gibberellin A₃ (GA₃) promotes and abscisic acid (ABA) inhibits the production of α -amylase in aleurone layers of barley (*Hordeum vulgare* L.); this system has been used extensively to study the mechanisms of action of these hormones¹. Cell-free messenger RNA translation studies have shown that the GA₃-promoted increase in α -amylase synthesis and its inhibition by ABA are associated with corresponding changes in the levels of translatable α -amylase mRNA²⁻⁵. Subsequent studies using hybridization of an α -amylase complementary DNA-rich probe⁶ and of cloned α -amylase cDNA probes to aleurone RNA⁷⁻⁹ have shown that the abundance of α -amylase mRNA increases in response to GA₃, and that this increase is inhibited by ABA. The increased abundance of mRNA could result from an increased rate of transcription, increased stability of mRNA, or both, as in some animal cells¹⁰⁻¹². By using methods for studying gene transcription in isolated plant nuclei¹³⁻¹⁵, we present here evidence that GA₃ and ABA regulate the transcription of both α -amylase and ribosomal RNA (rRNA) genes

Nuclei were isolated from GA₃-responsive aleurone cell protoplasts¹⁶ and to facilitate this, several minor changes were made to our earlier protoplast preparation procedure. Figure 1 shows that, using the modified procedure, very little α -amylase activity accumulated in control protoplasts, that there was a marked

Fig. 1 Regulation of α -amylase produced by barley aleurone protoplasts in response to GA₃ and ABA

Methods. Protoplasts were prepared from aleurone layers of barley (*H. vulgare* cv. Himalaya) under nitrogen as in an earlier study¹⁶ but 20 quarter grains, not 10, were placed in each Erlenmeyer flask and the volume of protoplast isolation medium containing cellulase Onozuka R-10 was increased from 1 ml to 1.5 ml, this procedure gave about 500,000 protoplasts per flask. Flasks received 100 μ l of either water (control, ■) or a solution of GA₃ (final concentration 1 μ M, ●) or GA₃ plus *cis*, *trans*-ABA (final concentration 25 μ M) (○) and were left without shaking at room temperature ($22 \pm 2^\circ\text{C}$). Assay and expression of α -amylase activity have been described elsewhere¹⁶. Values represent the mean of four flasks of protoplasts.

Fig. 2 Comparison of the effects of hormones on accumulation of total (a) and various specific transcripts (b-d) in isolated nuclei. b, rRNA; c, α -amylase; d, RNA specified by pHV14. The relative values for each RNA species were calculated from the values of c.p.m. per 100 μ g DNA given in Table 1. c, control nuclei; GA₃, nuclei from GA₃-treated protoplasts; GA₃ + ABA, nuclei from protoplasts treated with both GA₃ and ABA.

* Present address Pioneer Hi-Bred International Inc., Plant Breeding Division, Department of Biotechnology Research, 7300 N-W 62 Avenue, Box 38, Johnston, Iowa 50134, USA

Table 1 Accumulation of transcripts by nuclei isolated from barley aleurone protoplasts incubated for 24 h with and without GA₃ and ABA

	Control	GA ₃	GA ₃ + ABA
Total transcription	7,530 (100)	3,712 (100)	8,075 (100)
rRNA	1,355 (18)	360 (9.7)	1,574 (19.5)
α -Amylase transcripts	0.25 (0.0033)	1.37 (0.037)	0.32 (0.0040)
pHV14 transcripts	0.17 (0.0023)	2.52 (0.068)	0.89 (0.011)

The values are (c.p.m. per 100 μ g DNA) $\times 10^{-3}$ and the numbers in parentheses are percentages of total transcription. Protoplasts were prepared and incubated for 24 h with and without hormones as described for Fig. 1 (10 flasks per treatment). Because starch grains interfered with the protoplast lysis procedure (see below), protoplasts were purified on discontinuous Percoll gradients made essentially as described by Luthe and Quatrano¹⁹. The gradients consisted of 5-ml layers of 2 M sucrose (bottom), and of 80% and 15% Percoll in 30-ml Corex centrifuge tubes. The Percoll was made up in 0.44 M sucrose (RNase-free, Bio-Rad), 25 mM Tris-HCl pH 7.5 and 10 mM MgCl₂. The contents of five incubation flasks were layered onto each gradient (on ice) and the tubes were centrifuged at 4,080g (5,000 r.p.m. in a Sorvall HB4 swinging bucket rotor) for 20 min. The protoplasts band at the top and bottom of the 15% Percoll layer, the starch falls to the bottom of the tube, and the dead protoplasts float to the top of the original protoplast medium. The entire 15% Percoll layer was recovered and diluted with an equal volume of 0.44 M sucrose, 25 mM Tris-HCl pH 7.5, 10 mM MgCl₂, 5% w/v Ficoll and 10% w/v Dextran 40. To this mixture was added 1 μ l ml⁻¹ β -mercaptoethanol, 0.5% (v/v) Triton X-100 and 2 mM spermine; the cells were then contained in a solution similar to the modified Honda medium of Luthe and Quatrano¹⁹. The protoplasts were broken by passing the suspension five times through nylon mesh with nominally 20- μ m pores (actually 13 μ m when measured). The nuclei were recovered from solution by centrifugation (3,000 r.p.m. for 10 min in an HB4 rotor) and washed twice in 10 ml of 2.5% Ficoll 400, 5% Dextran T40, 0.25 M sucrose, 0.025 M Tris-HCl pH 7.8, 0.01 M MgCl₂ and 1 μ l ml⁻¹ β -mercaptoethanol. Pellets were resuspended gently using a glass rod and centrifuged at 3,000 r.p.m. in an HB4 rotor for 5 min. The washed pellet derived from 10 flasks of protoplasts was resuspended in ~150 μ l (total volume) of the washing buffer. Transcription reactions were started by adding 120 μ l of nuclei (usually containing ~80 μ g DNA) to 600 μ l of transcription mixture. Final concentrations of components were: 50 mM (NH₄)₂SO₄, 0.45 mM each of ATP, GTP and UTP, and 2 mM MnCl₂. Each reaction contained 300 μ Ci [α -³²P]UTP (specific activity ~3,000 Ci mmol⁻¹; Amersham). Attempts to use [α -³²P]GTP to radiolabel RNA were unsuccessful because transcription was progressively more inhibited as the amount of radioactive GTP in the reaction was increased. The reactions were incubated at 20 °C for 1 h. To measure accumulation of total RNA, aliquots of the reaction mixture were taken at the beginning and end of the reaction and the nucleic acid was precipitated with cold trichloroacetic acid (TCA) in the presence of carrier herring sperm DNA and the radioactivity in RNA determined as described previously¹⁷. To measure specific gene transcripts, the RNA was first extracted from the nuclei. The nuclei, containing 94% of the TCA-precipitable radioactivity, were recovered from the reaction mixture by centrifugation and the RNA was purified essentially as described elsewhere¹⁷, except that the proteinase K and sonication steps were omitted. The ethanol-precipitated nucleic acid was centrifuged and dissolved in 50 μ l of 0.1% SDS, 0.5 mM EDTA and 1 mM Tris-HCl pH 7.5. Recombinant plasmids used to detect specific transcripts were pTA71, containing wheat genomic ribosomal DNA²⁰; pHV19, containing sequences for barley aleurone α -amylase⁹, and pHV14, which is unidentified but contains sequences for a barley polyadenylated RNA species whose concentration increases in the presence of GA₃, as does α -amylase mRNA⁹. The control plasmid was pP15-71, which contains *Psidium sativum* cDNA sequences specific for vicilin²¹. Plasmid DNA (2 μ g) was bound to nitrocellulose filter disks (6.5 mm diameter) by the method of Thomas²². Hybridizations were performed as described previously¹⁷, except that rRNA hybridizations were done in 30 μ l and the others in 100 μ l. All hybridizations contained a pP15-71 filter for the determination of background radioactivity, which was subtracted from that binding to other filters in the hybridization. Hormone treatments did not affect the recovery of DNA from protoplasts but, because they did affect total transcription, hybridized counts have been expressed both as a percentage of total transcriptional activity and as c.p.m. per 100 μ g DNA ($\times 10^{-3}$), as described previously¹⁷.

response to 1 μ M GA₃ and that a 25-fold excess of ABA over GA₃ strongly inhibited α -amylase accumulation, at least up to 48 h, at which time accumulation of the enzyme appeared to be released from ABA control. From these results, we chose to isolate nuclei for *in vitro* transcription experiments from protoplasts incubated with or without hormones for 24 h, as at this time, ABA is strongly inhibitory and the rate of α -amylase accumulation is still increasing. Previous studies indicated that an increasing rate of α -amylase accumulation is associated with increasing levels of α -amylase mRNA^{2,5}. If the increasing levels of α -amylase mRNA are the result of increased transcription of the α -amylase genes, then 24 h should be a suitable time to detect it.

Initially, nuclei were isolated from protoplasts which had been incubated for 24 h with and without GA₃ and ABA (as in Fig. 1) and their capacity for transcription *in vitro* was determined. All nuclei preparations incorporated nucleoside triphosphates into RNA for 1 h, after which acid-precipitable RNA was slowly lost, presumably as a result of ribonuclease activity (data not shown). Accordingly, all transcriptions were run for 1 h, at which time total incorporation of [α -³²P]UTP into RNA reached maximal levels of up to 80,000 c.p.m. per μ g DNA, depending on the treatment (see below).

To determine the effects of hormones on the accumulation of total transcripts and on the accumulation of specific gene transcripts in isolated nuclei, protoplasts were incubated with or without hormones for 24 h, and their nuclei were isolated and allowed to transcribe *in vitro*. The *in vitro*-synthesized RNA was hybridized to specific cloned DNAs (see Table 1). The results in Table 1 are from one experiment but they are representative

of results obtained in two other experiments. Incorporation of [α -³²P]UTP into total RNA was decreased in nuclei isolated from protoplasts treated with GA₃ compared with the level in nuclei from control protoplasts. This decreased incorporation did not occur when protoplasts were treated with ABA in addition to GA₃ (Table 1). Because the concentration of UTP added to the transcription reaction was very low (0.12 μ M), these results could be explained by hormone-mediated effects on the size of the residual UTP pool in isolated nuclei. However, experiments using UTP concentrations 77 times greater showed the same effects of the hormones on total RNA accumulation. Thus, the hormonal effects are not artefacts resulting from changes in specific radioactivity of the *in vitro*-synthesized RNA.

In the above experiment, the rRNA transcripts contributed 18% of the total transcripts in nuclei from untreated protoplasts although in other experiments their contribution was as low as ~6%. The range of these values is similar to that reported for pea leaf nuclei¹³ but considerably less than the range for pea cotyledon nuclei, which was ~45 to 77% (ref. 17). The accumulation of rRNA transcripts in this and other experiments was depressed by about 50% in protoplasts treated with GA₃ but this did not occur if ABA was also present.

The hormones also had large effects on the accumulation of α -amylase gene transcripts. In accordance with the very low level of α -amylase activity and α -amylase mRNA in control protoplasts¹⁶, there was very little accumulation of α -amylase gene transcripts in control nuclei; when GA₃ was present, however, accumulation of the transcripts increased about 11-fold to a level of 0.037% of total transcription. Incubation of proto-

plasts with ABA in addition to GA₃ once again inhibited the effect of GA₃. The α -amylase cDNA clone pHV19 probably corresponds to mRNA for the B group of α -amylase isozymes⁹. We believe that in the hybridization conditions of the present experiments, transcripts of both A and B α -amylase families will hybridize to pHV19 because of the relatively high nucleotide sequence homology between group A and B cDNA clones and because of their high G+C content⁹. Therefore, the α -amylase gene transcripts measured here probably represent the composite contribution of several α -amylase genes, estimated to be at least eight in the *H. vulgare* cv. Himalaya genome^{7,9}. Our results do not allow us to determine whether or not GA₃ regulates the transcripts of all genes equally.

We also measured the accumulation of transcripts specific to clone pHV14 because it specifies a mRNA whose abundance also increases in the presence of GA₃, as does α -amylase mRNA, although we have not identified any protein that it encodes⁹. The effects of GA₃ and ABA on the synthesis of RNA hybridizing to pHV14 were similar to their effects on α -amylase gene transcription (Table 1).

These results leave little doubt that GA₃ and ABA regulate nuclear activity in barley aleurone cells. The most likely explanation for the results is that the hormones regulate specific gene transcription and thus mRNA formation, although it is still possible that altered transcript stability and processing within the nucleus may be involved. The accumulation of α -amylase gene transcripts was increased about six times in nuclei from GA₃-treated protoplasts although in other experiments it was increased by up to 14 times. The variation in the extent of the increase of α -amylase gene transcripts with GA₃ treatment probably reflects the small and variable numbers of hybridizable counts in RNA accumulated by control nuclei. It is of interest to examine whether the hormone-promoted increase of α -amylase transcripts could account for the observed changes in level of α -amylase caused by GA₃. The rate of α -amylase accumulation after 24 h was increased from ~0.053 units h⁻¹ to ~0.63 units h⁻¹, an increase of a factor of ~12 (Fig. 1). Although these values are approximate, the increased concentration of α -amylase gene transcripts is clearly in accord with the increased rate of α -amylase accumulation. However, more detailed studies of rates of gene transcription, mRNA levels, mRNA stability and rates of enzyme synthesis are necessary to determine whether GA₃ controls α -amylase synthesis solely by regulating gene transcription.

A review of the literature shows that ABA has been found to reverse all of the GA₃-promoted changes in protein synthesis or mRNA levels in barley aleurone, whether they be increases or decreases¹. The results of the present study add to that list. ABA not only prevents the GA₃-promoted accumulation of α -amylase gene transcripts and of pHV14 transcripts in nuclei, but also prevents the suppression of total transcripts and of ribosomal transcripts by GA₃. Thus, the action of ABA leads to both promotion and inhibition of transcription and in this respect resembles GA₃. In summary, these experiments indicate that the inhibitory effect of ABA on α -amylase synthesis and on the accumulation of α -amylase mRNA²⁻⁹ can be accounted for largely by its effects within the nucleus, probably on gene transcription. A cytoplasmic role for ABA, in particular at the level of translation¹, in the conditions of these experiments would appear to be unnecessary.

These results also exemplify the complexity of GA₃ action. GA₃ has multiple effects in cereal aleurone, increasing the concentration of some mRNAs and proteins and decreasing the concentration of others^{5,18}. Here against a background of reduced total transcripts, GA₃ caused suppression of ribosomal gene expression and an increased expression of two other genes (Fig. 2). It seems, therefore, that the multiplicity of effects elicited by GA₃ on protein and RNA levels is also seen at the level of transcription.

We thank Dr Peter Chandler for helpful discussions during this work and for providing cDNA clones pHV19 and pHV14. We also thank Rosemary Metcalf for technical assistance.

Cooperative dimeric and tetrameric clam haemoglobins are novel assemblages of myoglobin folds

Baltimore, Maryland 21218, USA

Cooperative functioning of many protein systems depends on communication between different subunits of those systems. Perhaps the best understood cooperative protein system is the vertebrate haemoglobin tetramer, in which the subunits share a similar tertiary structure (the myoglobin fold) with each other and with myoglobins and haemoglobins from at least four different animal phyla and leguminous plants. Blood clams have cooperative tetrameric haemoglobin and, in addition, a cooperative homodimeric haemoglobin¹⁻⁶. In view of previous reports^{7,8} concerning the role of dimers in the vertebrate tetramer, the clam haemoglobins represent a very interesting model system. We report here the low-resolution three-dimensional crystal structures of the dimeric and tetrameric cooperative haemoglobins from the blood clam *Scapharca inaequivalvis*. We find that clam haemoglobins are made of myoglobin-like subunits but their assembly to form dimers and tetramers is quite different from that of vertebrate haemoglobin. The arrangement of the subunits provides a simple structural explanation for haem-haem interaction in the dimer and tetramer.

The haemoglobins in *S. inaequivalvis* are formed from three distinct polypeptide chains, two of which associate to form heterotetramers (A₂B₂), while a third associates to form homodimers⁵. The dimers and tetramers bind oxygen cooperatively with Hill coefficients of 1.5 and 2.1, respectively⁶. The dimer shows no oxygen-linked subunit association phenomena, whereas the tetramer can associate to form higher polymers in the deoxy state⁵. Although complete amino-acid sequences are not available for the haemoglobins from *S. inaequivalvis*, the sequences of two haemoglobin chains from related clams have been determined^{9,10}; these sequences align functionally with sequences from other haemoglobins that possess the myoglobin

Fig. 1 Composite sections from the 5.5-Å clam tetramer map (A, B, D, E), with equivalent sections from a 5.5-Å map of the α -chain of human CO haemoglobin (C, F). The Fourier coefficients for the map of the human α -chain were calculated from atomic coordinates obtained from the Protein Data Bank¹⁸ with an overall B value of 20 Å². A, B, the haem and E and F helices of the two distinct subunits in the clam tetramer map; C, the equivalent region from the structure factor map of the human α -chain. These density 'slabs' cover four sections or ~ 5.5 Å perpendicular to the plane of the paper. D, E, the G and H helices of the two distinct subunits in the clam tetramer map, F, those of the human α -chain. These density slabs cover six sections or ~ 9.2 Å perpendicular to the plane of the paper. Note particularly the additional electron-dense rod in the upper portion of D and E corresponding to the pre-A helix which is present in clam haemoglobin but not in other haemoglobins. The G helix density shown in E is the poorest density obtained for a helix in the tetramer map (The G helix is on the outside of the molecule in the clam tetrameric haemoglobin).

Fig. 2 Stereo diagrams showing arrangement of subunits in the clam haemoglobin dimer (A), clam haemoglobin tetramer (B) and human haemoglobin tetramer (C). The pre-A, A, B, E, F, G and H helices are drawn with heavy lines. The diagrams for the clam haemoglobins were drawn using helix end points taken from the tetramer map. The human CO haemoglobin diagram uses the α -carbon positions of residues at the end of helices, obtained from the Protein Data Bank coordinates. One subunit in both the clam dimer and tetramer is labelled N at the amino terminus and C at the carboxy terminus. A, clam dimer with the dyad relating the two subunits oriented perpendicular to the plane of the paper. Note how the E and F helices of the two subunits lie across each other to form an extensive contact. (The E and F helices are labelled in one subunit.) The slightly different chain path for the two subunits in the homodimer diagram is the result of the molecular replacement model and does not represent any real difference between the subunits. B, clam tetramer with the molecular dyad (used in symmetry averaging) oriented horizontally in the plane of the paper and the pseudo-dyad relating the two subunits within a dimer, also approximately in the plane of the paper. C, human CO haemoglobin tetramer with the molecular dyad lying horizontally in the plane of the paper and the pseudo-dyad relating α_1 to β_1 lying vertically in the plane of the paper. In vertebrate haemoglobins the pseudo-dyad is perpendicular to the molecular dyad and together they generate a third dyad. Thus, vertebrate haemoglobin has approximate 222 point group symmetry. In the clam tetramer these dyads are not perpendicular, a third perpendicular dyad is not generated, and thus the clam tetramer does not have approximate 222 point group symmetry.

Fig. 3 The packing of dimeric and tetrameric clam haemoglobins in their crystals. Line drawings of the subunits as in Fig. 2. *A*, seven tetramers projected down *b*; the most extensive contact is between the central tetramer and the one at the lower right. *B*, seven tetramers projected down *a*. A fairly extensive contact can be seen between the central tetramer and that at the upper right, which is related to it by a crystallographic dyad axis. The space group symmetry and packing considerations are incompatible with these contacts being intramolecular. *C*, twelve dimers projected down an axis 30° away from *b*. The *b* axis is oriented into the paper, to the right. The tight association occurs across the crystallographic dyad axis along *b*. *D*, close-up of two dimers related by the crystallographic dyad along *b*, which is vertical in the figure. *E*, close-up of the tetramer with the molecular dyad vertical. Note that the dimers associate in dimer crystals much as do the half-molecules in the tetramer, but the two dimers are slightly less tightly packed than are half-molecules in the tetramer. The distances between iron atoms in neighbouring dimers are 47.5–52.5 Å, whereas the corresponding distances in the tetramer are 45.5–49.1 Å.

fold, and, in common with the hagfish, lamprey and shark, they have additional residues at the amino terminus.

The haemoglobin used in the present study was provided by Dr E. Chiancone (University of Rome). Table 1 shows data on crystal preparation and lattice constants for both dimeric and tetrameric carbon monoxide haemoglobins. Both types of crystal are robust in the X-ray beam and diffract well past 3 Å resolution.

A 5.5-Å electron density map of the tetramer crystals was calculated using phases obtained from isomorphous and anomalous differences for uranyl acetate and gold cyanide derivatives and from isomorphous differences for a potassium *cis*-dichlorodiamine platinate derivative. The 'phasing power' ($\langle f_H \rangle / (\text{error of closure})$) for the uranium, gold and platinum derivatives was 2.2, 1.6 and 1.1, respectively. The mean figure of merit was 0.79. This map contained many electron-dense rods, presumably corresponding to α -helices. The probable molecular envelope was established by considering the relatively empty solvent regions in combination with the packing constraints imposed by the location of the symmetry elements of the space group. Tentative iron positions, which subsequently proved to be correct, were identified by high electron density and small but consistent peaks in anomalous difference Fourier

Table 1 Dimeric and tetrameric crystal growth and lattice data*

	Buffer	pH	Space group	<i>a</i>	<i>b</i>	<i>c</i>	β	<i>z</i>
Dimer	2.5 M PO ₄	7.5	C2	93.3	44.1	83.6	122.0	1
Tetramer	2.4 M PO ₄	5.8	C222 ₁	102.1	94.1	128.0	—	1

maps for both the gold and uranium derivatives. Perhaps most importantly, we found a non-crystallographic molecular dyad relating the two gold sites, two minor uranium sites and most of the electron density in its neighbourhood. Eleven cycles of symmetry averaging about this dyad dramatically improved the quality of the map. The *R*-value for the final symmetry-averaged map was 21.4% ($R = \sum |F_o - F_c| / \sum F_o$). The details of the determination of the tetramer and dimer structures will be published elsewhere.

In the final symmetry-averaged map, four myoglobin-fold subunits are evident. Each polypeptide chain can be followed with, at most, three short breaks. Each subunit contains an ellipsoid of very high density between the E and F helices, which corresponds to the haem group (see Fig. 1). An additional electron-dense rod ~ 18 Å long extends from the end of the A helix to the amino terminus of each chain; we believe this to be a helix and call it 'pre-A'. The pre-A helix is roughly parallel to, and in the same plane as, the G and H helices (see Fig. 1). It runs between the E–F corner and the H helix, and, in all subunits, the amino terminus is within 10 Å of the carboxy terminus. In retrospect, the pre-A helix made interpretation of the initial electron density maps difficult because in no other myoglobin folds do subunits have three roughly parallel helices. Other than the pre-A helix, the subunits have standard myoglobin folds.

The most striking feature of the clam tetramer structure is the manner in which the subunits are assembled. In vertebrate tetrameric haemoglobins, the G and H helices are on the inside of the molecule and are involved in subunit interactions, whereas the E and F helices are on the outside of the molecule and are exposed to solvent. However, in the clam haemoglobin tetramer, all the G and H helices are on the outside of the molecule and are exposed to solvent, whereas the E and F helices are involved in subunit interactions. Thus, the clam tetramer is 'back-to-front' relative to the vertebrate haemoglobins (see Fig. 2). The tetramer is a dimer of dimers with one dimer related to the other by the molecular dyad mentioned above. Within a dimer, the E–haem–F surfaces of the subunits face each other, forming an extensive contact.

The dimer contact involving the F helix invites speculation about the molecular basis of the cooperativity. In the deoxy form a contact similar to that seen in the liganded structure may clamp the subunits in a low-affinity state. In human haemoglobin, the F helix is displaced ~ 1 Å on CO binding¹¹, while in sperm whale myoglobin, the F helix is displaced by ~ 0.3 Å on oxygen binding¹². If displacements of the F helix occur in the clam haemoglobin subunits, binding of oxygen to one subunit would disrupt the deoxy contacts and allow the molecule to 'relax' to a partially liganded structure in which the unliganded haems have a higher affinity than those clamped in the deoxy structure.

Before the determination of the tetramer structure, we had little success with the dimer crystals. Lack of sufficient dimer crystals limited our heavy-atom search and we did not obtain any satisfactory molecular replacement solutions using various search molecules. However, on observing the back-to-front mode of association of the dimers in the tetramer structure, we speculated that the cooperative homodimer might be assembled similarly. A dimer constructed in this way could be cooperative, and from a balsa-wood model it appeared that the contacts were sufficiently extensive to be stable. In addition, a comparison of the sequences of a tetramer chain from *Anadara trapezia*⁹ with those of the dimer chain from *Anadara broughtonii*¹⁰ shows that although only 42% of the residues are identical in both chains,

84% of the residues in the E and F helices are identical. This result implies that the residues in the E and F helices are conserved between the tetramer and dimer chains for some important purpose such as contact formation.

Thus, we decided to use the dimer electron density from our tetramer map as a search molecule in molecular replacement. Structure factors obtained from the inverse Fourier transform of the isolated density were used in rotation¹³ and translation¹⁴ function calculations against the dimer data. Unlike our previous molecular replacement calculations, these gave good solutions.

We tested the validity of this molecular replacement solution using various criteria. First, the *R*-value of 42.8% compares favourably with other successful solutions^{15,16}. Second, dimer placement in the crystal showed no interpenetration between neighbouring molecules even though packing considerations were not included in the translation function (see Fig. 3). In addition, standard difference and 'haem-less'¹⁵ difference Fourier maps were calculated, examined and found to support this solution. Finally, an anomalous difference Patterson¹⁷ for native dimer crystals contained peaks at all positions for the expected iron-iron vectors.

The 'cooperative dimer' hypothesis of Antonini⁷ and colleagues in the late 1960s has been shown to be inapplicable to vertebrate haemoglobin⁸, in which the uncooperative $\alpha_1\beta_1$ dimer appears to move as an essentially rigid body. However, dimeric clam haemoglobin is cooperative, and a probable structural basis for that cooperativity has been revealed in the crystal structure. Because the same mode of subunit assembly occurs in the tetramer, it is likely that Antonini's cooperative dimer is

the underlying cause of cooperativity also in tetrameric clam haemoglobin.

To ascertain how these structures change with the release of ligands and why the dimers do not form tetramers in solution, we intend to determine the structures of liganded and deoxy dimeric and tetrameric clam haemoglobins at high resolution.

We thank Drs Emilia Chiancone and Eraldo Antonini for drawing our attention to these interesting proteins and for providing us with purified dimeric and tetrameric haemoglobins; and Drs Janet Smith and Wayne Hendrickson for the symmetry-averaging programs and many helpful discussions. This work was supported by NIH grant AM 02528. W.E.R. was supported in part by NIH training grant GM 07231.

MATTERS ARISING

A complex of copper (II)-montmorillonite with a modified cyclodextrin

IN the article by Kijima *et al.*¹, structural organization of intercalated mono-(6- β -aminoethylamino-6-deoxy)- β -cyclodextrin (CDen) has been deduced from the interpretation of electron paramagnetic resonance (EPR) spectra of oriented film samples (CDen-Cu(II)-montmorillonite).

However, the invariance of the EPR spectrum towards the variation of the angle between the film plane and magnetic field is indicative of a random orientation of the adsorbed Cu(II) complexes rather than a spatial organization. For both models proposed in Fig. 3a and b, there should be a pronounced angular dependence of the spectrum with a maximum change at 45° in 'structure a' and a vanishing component at 90° in 'structure b'.

Since the statements in this article are inferred from an erroneous spectrum interpretation, the conclusions about the lipid bilayer orientation remain questionable.

HERBERT MOTSCHI

Eidgenössische Technische
Hochschulen,
EAWAG, CH-8600 Dübendorf,
Switzerland

KIJIMA *ET AL.* REPLY—We admit that we have misinterpreted the electron spin resonance (ESR) spectra given in Fig. 2 of our paper. It is true that these spectra are indicative of a random orientation of the adsorbed Cu(II) complexes rather than a spatial organization, as pointed out by Motschi. This indication, however, appears impossible in view of the stereochemistry of hydrated Cu(II) ions in Cu(II)-montmorillonite¹. By using X-ray diffraction and scanning electron microscopy, we have re-examined the orientation of silicate layers in the film of CDen-Cu-montmorillonite used for ESR measurements. This re-examination leads us to conclude that the ESR spectra in Fig. 2 should be for a randomly oriented sample, not for an oriented film.

In considering the arrangement of intercalated CDen, ESR observations were used to justify two assumptions: (1) that the interlayer Cu(II) ion forms a coordination group [Cu(II) (*en*) (H₂O)₂]²⁺ with a square configuration and (2) that this square plane is perpendicular to the silicate layers. The correct data support assumption (1), but are inefficient in proving the other. However, it does not mean that the structure model proposed is invalidated. This is because it seems reasonable to adopt the second assumption, and because the structure model was fundamentally deduced from the interpretation of data for the interlayer spacing

and chemical composition of CDen-Cu-montmorillonite. Thus, our conclusions about the lipid bilayer orientation remain unchanged.

Matters Arising

Matters Arising is meant as a vehicle for comment and discussion about papers that appear in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted. Neither contribution nor reply (if one is necessary) should be longer than 500 words and the briefest of replies, to the effect that a point is taken, should be considered.

Why this magazine and more than 1,000 others let us go over their books once a year.

Some magazines, we're sorry to say, keep their readers undercover. They steadfastly refuse to let BPA (Business Publications Audit of Circulation, Inc.) or any other independent, not-for-profit organization audit their circulation records.

On the other hand, over 1,000 publications (like this one) belong to BPA. Once a year, BPA auditors examine and verify the accuracy of our circulation records.

This audit provides the name, company, industry and job title of every reader each publication reaches. The information helps advertisers to determine if they are saying the right thing to the right people in the right place.

It also helps somebody else important: you. Because the more a publication and its advertisers know about you, the better they can provide you with articles and advertisements that meet your informational needs.

BPA. For readers it stands for meaningful information. For advertisers it stands for meaningful readers. Business Publications Audit of Circulation, Inc.

CAMBRIDGE
MRC Laboratory of
Molecular Biology
POST-DOCTORAL
SCIENTIST

Applications are invited from post-doctoral scientists to work with Dr. Tom Creighton on genetic engineering of a small protein for structural and folding studies. Experience of genetic manipulation techniques and protein chemistry will be advantageous but not essential.

The post is available for 3 years and the salary will be in the range £3,920 — £14,925 pa.

Applications — including a full CV, a short statement of relevant experience, and the names of two professional referees — should be sent by (8th August 1985) quoting reference BL/8 to: The Assistant Director (Administration), MRC Laboratory of Molecular Biology, Hills Road, Cambridge CB2 2QH. (7130)A

UNIVERSITY OF
LIVERPOOL
DEPARTMENT OF BOTANY
Applications are invited for an
SERC postdoctoral
SENIOR RESEARCH
ASSISTANT

tenable for twelve months at a salary of £7,520 per annum.

The project is an investigation of the ionic relations of the green alga *Dunaliella*. A knowledge of the use of radio-isotopes and the techniques of electro physiology would be helpful.

Informal enquiries may be made to Dr. J.C. Collins, Tel: 051-709 6022 Ext: 2400.

Applications, together with the names of three referees, should be received as soon as possible by The Registrar, The University, P.O. Box 147, Liverpool, L69 3BX from whom further particulars may be obtained.

Quote Ref: RV/153/N. (7141)A

THE MIDDLESEX
HOSPITAL
MEDICAL SCHOOL

RESEARCH WORKER

Research worker required to participate in project on renal disease (hyperfiltration syndromes). The ability and dedication to carry out high precision radioimmunoassays (RIA) will be essential and familiarity with RIA and computer handling of data, an advantage. The project is suitable for work towards a higher degree. Salary up to £8,753, according to age and experience. The position is available for 3 years (first six months are a probationary period).

Applications with full cv and names and addresses of 2 referees should be sent not later than 31 July 1985 to: The Administrative Officer, The Middlesex Hospital Medical School, Cleveland Street, London W1P 7PN. (7151)A

THE UNITED MEDICAL
AND DENTAL SCHOOLS

Guy's Campus — Paediatric
Research Unit

Human Genetic Diseases

RESEARCH ASSISTANT

required to join a project investigating the basic defect in Cystic Fibrosis. The post will involve a biological and biochemical analysis of specific epithelial cell types. Experience of cell culture techniques is essential.

The post will be for a period of two years. Initial salary up to £6,600 pa plus £1,233 pa London Allowance.

Applications, including full Curriculum Vitae and names of two referees, to the Administrative Assistant, The Prince Philip Research Laboratories, Guy's Tower, London SE1 9RT. (7119)A

PARKE-DAVIS RESEARCH UNIT

CAMBRIDGE

DIRECTOR: Dr John Hughes

RESEARCH ASSOCIATE IN PHARMACOLOGY

The Unit is developing new generation drugs for the treatment of nervous and neurohormonal disorders. Our basic research interests centre on the function and mechanism of action of hormones and neurotransmitters at the behavioural, cellular and molecular levels with particular reference to peptides. The Unit is a unique example of academic and industrial collaboration aimed at solving problems of fundamental importance to human health.

Applications are invited from experienced research pharmacologists ideally with expertise in isolated tissue techniques. Applicants should have at least three years postgraduate research experience preferably within the pharmaceutical industry, or hold, or expect to obtain by 1st October, a Ph.D in a relevant pharmacological area.

The position will carry a starting salary in the range £9,600 - £11,000 depending on experience. Other benefits include relocation assistance where appropriate.

Applications should be accompanied by a full up-to-date c.v. describing experience and research interests, together with the names of two scientific references and sent to Dr. Chris Bruton, Parke Davis Research Unit, Addenbrookes Hospital Site, Hills Road, Cambridge CB2 2QB to arrive as soon as possible but in any event by 3rd August 1985.

WARNER
LAMBERT

UNIVERSITY C
FACUL

Medical Science and Clinical Appointments

Applications are invited for the following appointments in the Faculty of Medicine

Anatomy

- a Assistant/Associate Professor in Gross Anatomy — 1 pc
Candidates should have teaching experience in Topographic Anatomy. Current and active research experience may be in the areas of Neuroanatomy, Histology, Growth and development or Gross Anatomy

Psychiatry

- a Associate Professor — 1 pc
Candidates should have experience in teaching and/or research in clinical psychiatry, preference will be given to suitable candidates who speak Arabic
b Assistant Professor — 1 pc

Medicine

- a Associate/Full Professor in Dermatology — 1 pc

Paediatrics

- a Associate Professor — 2 pos
in Paediatric endocrinology Allergy or gastroenterology

Physiology

- a. Associate/Full Professor — 2 pos
Preference will be given to general systemic physiologists with balanced experience in teaching and research.

Pharmacology

- a. Associate/Full Professor in Toxicology — 1 pc
b. Associate Professor in Clinical Pharmacology — 1 pc
The applicant for the post of Toxicology should have experience in teaching and toxicological services, such as therapeutic drug monitoring and toxicological screening.

Surgery

- a Professor ENT — 1 pc
b Associate Professor ENT — 1 pc
c Associate Professor in Anaesthesia — 1 pc
d Associate Professor in Orthopaedic Surgery — 1 pc
Candidates for surgical posts should have at least 5 years clinical and teaching experience. They should also possess a Ph.D. or high professional medical qualifications (e.g. F.R.C.S.) in their respective fields.

Diagnostic Radiology

- a. Professor — 1 pc
b. Associate Professor — 2 pos
c. Assistant Professor — 1 pc
Experience in one or more of the following areas is needed, Body-CT, Orthopedic Radiology, Paediatric Radiology, GI and GU Radiology, and US Interventional Radiology.

Nuclear Medicine

- a Full Professor — 1 pc
b Assistant Professor — 2 pos
Experience and ability to teach are highly required. Candidates must have been involved in undergraduate and postgraduate teaching and basic and clinical research. Knowledge of computers applied to medicine is desirable.

Organ Transplantation

- a Assistant/Associate Professor in Transplantation Surgery — 2 pos
Applicants should have a background of general, vascular or urological surgery, possess the Fellowship of the Royal College or be certified by a recognised Board of Surgery or their equivalent. They should have 2 to 3 years of training in any area of clinical organ transplantation. For the Associate Professor another additional 3 to 4 years of practice in clinical transplantation surgery are required.
b. Assistant Professor in Experimental Surgery — 1 pc
Applicants should have a background in surgery or immuno-biology, possess a surgical Fellowship or a Ph.D. or equivalent and have 2 to 3 years of experience in surgical research preferably in an area related to Organ Transplantation.
c. Assistant/Associate Professor in Clinical Bone Marrow Transplantation — 1 pc
Applicants should have a background in haematology, oncology or immunology, with Postgraduate Fellowship, Membership or Certification in the specialty and have 2 to 3 years of training in Clinical Bone Marrow Transplantation. For the position of Associate Professor 3 to 4 years of experience in clinical Bone Marrow Transplantation will be preferred.
d Assistant/Associate Professor in Transplant Intensive Care — 1 pc
Applicants should have a background in Anaesthesia, Respiratory Care or Metabolism, possess the appropriate Fellowship, Membership or appropriate Board Certification or equivalent and have 3 to 4 years of experience in the field.

Biochemistry

- a. Associate Professor — 2 pos
b Assistant Professor — 1 pos

KUWAIT HEALTH SCIENCE CENTRE MEDICINE

Pathology

- Histopathology/Cytology
 - Full Professor — 1 post
 - Associate Professor — 1 post
 - Assistant Professor — 1 post
- Clinical Chemistry
 - Full Professor — 1 post
- Haematology
 - Associate Professor — 1 post

Microbiology

- Clinical Immunologist
 - Associate Professor — 1 post
 1. Candidate should be experienced in Clinical Immunology with a minimum of 3 years experience in the routine operation of a routine clinical immunology laboratory.
 2. Candidate should have a Ph.D./MD and Professional qualification e.g. M.R.C. Path or American Board or equivalent degree.
- Clinical Virologist
 - Professor/Associate Professor — 1 post
 1. Will be responsible for viral serology unit which mainly involves hepatitis and rubella serology. He will be responsible for cell culture laboratory, virus isolations and preparation of viral antigens and antiserum. Both jobs include teaching, research and clinical work.
 2. Clinical Virology experience. MD, Ph.D. MRCP or equivalent. Internationally known for work in clinical virology.

Virologist

- Associate Professor/Assistant Professor — 1 post
- Job description: Basic virology research, or molecular virology. Teaching undergraduates and postgraduates. Research in basic virology.
- Ph.D. with sound research experience

Community Medicine and Behavioural Sciences

- Associate Professor in Medical Psychology — 1 post
- Applicants should be able to demonstrate teaching and research competence. Preference will be given to candidates who have experience in teaching introductory and medical psychology courses to medical and allied health students, and who are interested in contributing to the development of postgraduate programmes.
- Associate/Full Professor in Epidemiology — 1 post
- Assistant/Associate Professor in Epidemiology — 1 post
- Applicant should be able to demonstrate teaching and research competence in the application of epidemiological methods to either etiological or health services development problems. The successful candidate is expected to take active part in undergraduate and postgraduate teaching, using field demonstration and small group teaching techniques. He would be encouraged to follow his own line of research in addition to assisting the Department, Faculty and Ministry staff in the design and conduct of quantitative studies.

Requirements for Appointment

Applicants should possess a Ph.D. or higher professional qualification, i.e. F.R.C.S., M.R.C.P. etc. in their respective speciality and have conducted and published research in their field. Professors should have 14 years' experience, 4 as an associate professor or its equivalent, i.e. senior lecturer or reader. Associate Professors should have 9 years' experience, 4 as an assistant professor or its equivalent, i.e. lecturer.

Conditions of Appointment

- Salaries: — Total monthly salaries will be within the following scales according to qualifications and experience (1 KD = £2.5, US\$3.2 approx.).
- Professors with clinical appointments = KD1210–KD1370 (8 increments).
- Professors medically qualified with medical science appointments = KD1140–KD1300 (8 increments).
- Professors non-medically qualified = KD1070–KD1230 (8 increments).
- Associate Professors with clinical appointments = KD989–KD1149 (8 increments).
- Associate Professors medically qualified with medical science appointments = KD932–KD1092 (8 increments).
- Associate Professors non-medically qualified = KD875–KD1035 (8 increments).
- Assistant Professors with clinical appointments = KD768–KD928 (8 increments).
- Assistant Professors medically qualified with medical science appointments = KD724–KD884 (8 increments).
- Assistant Professors non-medically qualified = KD680–KD840 (8 increments).
- Clinical Supplements: In addition to the above university salaries there will be monthly clinical supplement paid by the Ministry of Public Health for 10 months a year to medical school staff with clinical service commitments.
- These are:

Professor and Chairman	KD250,
Professor	KD200,
Associate Professor	KD150,
Assistant Professor	KD100.

Conference: A member is entitled to attend one academic conference a year which would be subject to the University rules and regulations.

Gratuity: There is a gratuity of one month basic salary for each year employed payable on termination of contract.

Housing: Suitable furnished, air-conditioned accommodation, electricity and water free of charge.

Medical care: Free, comprehensive treatment is available in Kuwait under the State Health Service.

Travel: Air tickets are provided from the country of recruitment for the appointee, spouse and up to 3 dependant children under 20 years. Hereafter, return air tickets are issued annually to the country of citizenship or permanent residence. On termination of contract, air tickets are provided to the country of recruitment. A baggage and freight allowance is also provided.

Vacation: 60 days paid annual leave and various national holidays.

Education: This is provided free in State Schools where the instruction is in Arabic. Staff who have to send their children to non-Arabic schools in Kuwait will have the tuition fees up to a maximum of 3 children met by the University.

Taxation: There is no income tax in Kuwait. Currency is transferable without restriction.

Method of Application

Curriculum vitae in duplicate which should include the names of 3 referees, personal particulars, qualifications with dates, career history, teaching experience, research accomplishments and where appropriate clinical experience should be sent to the Director of Planning and Academic Staff Recruitment, Faculty of Medicine, University of Kuwait, Health Science Centre, P.O. Box 24923, Safat, Kuwait, to arrive no later than 30th October, 1985.

(W2037)A

Astrophysics Group Leader

A vacancy exists at the Rutherford Appleton Laboratory for the Astrophysics Group Leader at Grade 6 (Senior Principal Scientific Officer) level. The work of the Group includes support of the University Community and research in the fields of x-ray, ultraviolet and infra-red astronomy and in solar physics

The duties of the Group Leader include: interface to the University Community involved in space projects supported by the Laboratory; the direction and co-ordination of the research programme in astronomy within the Laboratory; the management of the Group comprising of approximately 20 staff; provision of scientific support to instrument development and satellite project activities. He or she will also take responsibility for maintaining close links with the UK astronomical community, and with international agencies such as the European Space Agency and NASA

Within the Laboratory the Group Leader will be a member of a senior management team responsible for the implementation of the programme of the Astronomy, Space and Radio Board of the SERC at RAL.

QUALIFICATIONS AND EXPERIENCE:

The Group Leader will be expected to have an established reputation in a leading research team, for example as evidenced by a significant publication record, and will preferably have practical experience in space science or other relevant work

The appointment may be held on a permanent basis, or for a fixed term period of up to 5 years.

Salary range £17000 - £22926 per annum

The Rutherford Appleton Laboratory offers excellent working conditions and benefits including a good transport service and generous holidays. This is a pensionable appointment.

Contact Recruitment Office, Rutherford Appleton Laboratory, Science & Engineering Research Council, Chilton, Didcot, Oxon, OX11 0QX. Telephone Abingdon (0235) 445435 quoting Ref VN 359.

Closing date for applications: 9th August 1985.

(7178)A

The European Molecular Biology Laboratory, an international research organization situated in Heidelberg, West Germany, invites applicants for a position as

TECHNICAL ASSISTANT

The successful candidate will join a research group in our Cell Biology Programme and will carry out work on protein secretion, protein sorting and post-translational modifications of proteins

Applicants should be familiar with procedures used in tissue culture and monoclonal antibody production or protein purification and HPLC or molecular biology/molecular genetics. Knowledge of English or German as a working language is essential

An above-average salary will be offered to the successful candidate. Certain allowances are payable in addition, depending on personal circumstances. An initial contract of 3 years' duration, which can be renewed, will be offered

Please write briefly for an application form,

quoting reference
85/30 to

AND PHARMACOLOGY

Applications are invited for a post of

POSTDOCTORAL RESEARCH ASSISTANT

funded by the British Heart Foundation for a fixed period of two years from 1st October, 1985. The research work, with Professor Lamb's group, will include studies of the regulation of mammalian Na, K-ATPase specific mRNA in cultured and collagenase dispersed cell systems. Applicants should have experience with recombinant DNA and tissue culture techniques. Experience in the isolation of ventricular myocytes would also be advantageous.

Starting salary within range £7,520 — £8,920 per annum on 1A scale, according to age, qualifications and experience.

Applications (two copies preferably in typescript) with the names of two referees should be lodged by 31 July, 1985 with the Establishments Officer, The University, College Gate, St Andrews, Fife, KY16 9AJ.

(7121)A

MOLECULAR BIOLOGIST

New, modern research unit emphasizing protein chemistry is seeking an investigator interested in the structure and regulation of eukaryotic genes using recombinant DNA technology. Ph.D. or equivalent and relevant postdoctoral experience required. Available Fall 1985, this position is of indefinite duration dependent upon performance. Salary and rank will be commensurate with experience. If interested, send a current CV and a statement of research interests and goals to.

The
University of
Buckingham

Molecular Biologist and Cell Culture Scientist

Post Doctoral research in drug metabolism

Smith Kline and French Research have an exciting Post Doctoral Research Fellowship in Drug Metabolism and Pharmacokinetics to investigate fundamental aspects of the molecular biology of cellular toxicity and its relationship with the expression of drug-metabolising enzymes.

The work will be concerned with the study of factors affecting the expression of a defined drug metabolising system in vivo and in cell culture. Enzyme purification, antibody production, molecular cloning and possibly gene sequencing techniques will be involved.

Excellent academic and practical skills and the ability to apply novel, inventive approaches to problem solving are required. The post should appeal to molecular biologists and specialists in cell culture techniques who wish to apply their skills in a new field as well as to those who have previous experience in drug metabolism. Publication of scientific papers will be encouraged.

We offer competitive salaries and benefits for this 2/3 year fixed term appointment.

Please send a cv outlining your qualifications and experience to the Personnel Officer quoting reference number N/134/JDW, Smith Kline & French Research Limited, Research Institute, The Frythe, Welwyn, Herts AL6 9AR. (7177)A

UNIVERSITY OF GLASGOW

DEPARTMENT OF VETERINARY PATHOLOGY POSTGRADUATE RESEARCH ASSISTANT IN MOLECULAR BIOLOGY

Applications are invited from post-graduate scientists with a degree in molecular biology, microbiology, or a related discipline to work on an AFRC funded project to develop retrovirus vectors for gene insertion into embryos.

The successful candidate will have familiarity with, and an interest in current techniques in recombinant DNA technology.

In the first instance this post will be funded for 2 years from October 1985 on the 1B Scale

Applications, including a curriculum vitae and the names of two referees should be sent to Dr. D Onions, from whom further information may be obtained, at the Department of Veterinary Pathology, University of Glasgow Veterinary School, Bearsden Road, Bearsden, Glasgow G61 1QH. (7140)A

THE MEDICAL COLLEGE OF ST. BATHOLOMEW'S HOSPITAL (University of London)

Department of Biochemistry

Applications are invited for a post of

GRADUATE RESEARCH ASSISTANT

To work on electrostatic effects in enzyme catalysis using a wide range of kinetic, spectroscopic and protein chemical techniques applied to the cysteine proteinases, a group of homologous enzymes that provide natural structural variation in mechanistically relevant regions of the molecule. Applicants should have a First or Upper Second Class Honours degree in Biochemistry or Chemistry and would be expected to register for a higher degree. The post is funded by the SERC for 3 years from 1st October, 1985. Salary £7,833 — £8,753 including L.W. plus USS if required.

Applications with full curriculum vitae and names of two referees should be sent as soon as possible to Dr. K. Brickleyhurst, Department of Biochemistry, Medical College of St. Bartholomew's Hospital, Charterhouse Square, London, EC1M 6BQ. (7160)A

**INVERESK
RESEARCH
INTERNATIONAL**

DEPUTY HEAD — BIOTECHNOLOGY

Inveresk Research International Ltd. is one of the UK's largest independent contract research organisations. One of its main areas of activity is in contract Biotechnology. This is concerned with the development of novel product and processes in the health care, agricultural and food sectors. This group is in a phase of rapid expansion and now seeks to recruit a Deputy Head.

Research activities include extensive genetic engineering studies with microbial and mammalian vector systems, mouse and human monoclonal antibody developments, the design of novel immunodiagnoses, as well as traditional biochemical, genetical and enzymological studies. The appointee will, therefore, be expected to make a major contribution to the management of these areas and to provide the highest calibre of intellectual input to problem solving and innovative research in a highly competitive market place.

Applicants should have a sound knowledge of Biochemistry, Molecular Biology and Genetics, as well as a minimum of 10 years postgraduate experience. Proven ability in the management of a research team would be a prerequisite.

Salary for this appointment will be dependent upon qualifications and experience, and will reflect the importance of this position. In addition we offer a range of modern staff benefits including an excellent Pension & Life Assurance Plan, free private health care, as well as assistance with relocation expenses, where appropriate.

Full details in writing should be forwarded, in confidence, to the Personnel Department, Inveresk Research International Limited, Inveresk Gate, Musselburgh EH21 7UB, quoting reference 2544.

(7152)A

RESEARCH ASSOCIATE OR POSTDOCTORAL POSITIONS

Three positions available immediately for persons with training in molecular biology and nucleic acid biochemistry to work on the development of infectious vaccinia virus recombinant vaccines for viral diseases of cattle and to work on the expression of cloned cDNAs in prokaryotic and eukaryotic systems.

Salary: £17,000 to £25,000 depending on qualifications. Positions are funded for at least two years.

Send curriculum vitae and three letters of reference to: T. Yilma, Department of Veterinary Microbiology and Pathology, Washington State University, Pullman, WA 99164-7040; phone (509) 335-6042. Washington State University is an affirmative action/equal opportunity employer. Women and candidates from minority groups are encouraged to identify themselves as such.

(NW42)A

Postdoctoral Positions in Plant Molecular Biology

Two positions are available to study molecular biology of maize in an interdisciplinary project at the University of Minnesota. Research areas include transcriptional regulation of gene expression especially related to rRNA, zein or aspartate family pathway genes, and mitochondrial gene organization and expression.

Applicants must have completed the requirements for a Ph.D. by the time of appointment and should send a letter of intent, curriculum vitae, and statement of research experience and have 3 letters of recommendation sent to: Dr. B. Gengenbach, Dept. Agronomy and Plant Genetics, University of Minnesota, St. Paul MN 55108 by August 31, 1985.

The University of Minnesota is an Equal Opportunity Educator and Employer and specifically invites and encourages applications from women and minorities.

(NW48)A

THE DEPARTMENT OF PEDIATRICS University of California, San Diego

is recruiting for an

ASSISTANT PROFESSOR

In Residence in Neonatal/Perinatal Medicine

Position includes clinical supervision and teaching of housestaff and medical students, with unlimited opportunity for newborn research. Applicants must be board certified pediatrician or board qualified, with post-graduate training in neonatal/perinatology; licensed or licensable to practice medicine in the State of California; experience in teaching and clinical service; with research background. Salary commensurate with skills, knowledge, and University of California policy.

Candidates apply by August 15, 1985 with C.V. to Ronald Coen, M.D., Associate Professor of Pediatrics, Department of Pediatrics, UCSD Medical Center H-638-A San Diego, CA 92103. EEO/AA.

(NW43)A

BEATSON INSTITUTE FOR CANCER RESEARCH RESEARCH TECHNICIAN/ RESEARCH OFFICER

A new position for a research technician or research officer has arisen to work in a group studying the molecular control mechanisms regulating cell differentiation in the red blood cell system and how this becomes aberrant in certain leukaemias.

Applicants should have a good Honours degree in biochemistry, molecular biology or a related subject and/or technical experience in one of these areas. The position has long term funding and is an attractive position for someone highly motivated for a career in research. The position which is available from 1st October 1985 will be on MRC scales for research technicians or research officers (currently £5,952 — £8,096 or £6,483 — £8,492 respectively).

Interested applicants should send a full CV and the names of two academic references to Dr Paul Harrison, The Beatson Institute for Cancer Research, Garscube Estate, Switchback Road, Bearsden, Glasgow G61 1BD (Telephone: 041 — 942 9361).

(7136)A

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE (University of London) GRADUATE RESEARCH STUDENT

Applications are invited from students expecting to graduate in 1985 with at least 2:1 in Pharmacology, Physiology or related subject. The successful applicant will need to be confident in the use of quantitative approach. The research (supported by an Action Research project grant for a research assistant) involves investigation of the electro-physiology of neuromuscular transmission in myasthenic disorder using modern microelectrode techniques. The study is to be undertaken jointly by the Department of Pharmacology and Neurological Science during three year period, starting October 1985, and the applicant will be registered for a PhD.

Full curriculum vitae including names and address of two referees should be sent immediately to the School Office, RFHSM, Rowland Hill Street, London, NW3 2PF — please quote reference DW/GR. For further details telephone 794-0500 Extn 4330 or 4363. Closing date 2 August 1985.

(7132)A

THE DEPARTMENT OF PHYSIOLOGY University of Manitoba

invites applications from young investigators in the field
of

CARDIOVASCULAR PHYSIOLOGY

to be appointed at the level of Assistant Professor

The successful candidates will be expected to compete for local and national scholarship awards and develop their independent research programs. Applicants with backgrounds in membrane transport, electrophysiology, molecular biology or hemodynamics are encouraged to submit their curriculum vitae, an outline of their research interests as well as to arrange for three letters of reference to be sent to Dr. Henry G. Friesen, Professor and Head, Department of Physiology, Faculty of Medicine, University of Manitoba, Winnipeg, Manitoba, R3E 0W3 Canada. Deadline for application is 2 September 1985. The University of Manitoba is an Equal Opportunity/Affirmative Employer, but in accordance with Canadian Immigration, priority will be given to Canadian citizens and permanent residents of Canada. (NW12)A

PHYSICAL BIOCHEMISTS/MEMBRANE AND CELL BIOLOGISTS

The Thrombosis/Hematology Research Program of the Oklahoma Medical Research Foundation is seeking highly qualified M.D.'s and Ph.D.'s to participate in research related to the interactions of the serum complement, coagulation and fibrinolytic systems on membrane surfaces. Prior training and experience in protein chemistry, membrane biology, and/or the application of physical methods (e.g., *in vivo* fluorescence spectroscopy) to cell biology desired.

Suitable candidates will be expected to conduct full-time laboratory research in close interaction with the Thrombosis/Hematology Research Program. Funded positions available at all levels (postdoctoral and more senior positions) depending on experience.

Mail vitae and description of research interests to Peter J. Sims, M.D., Ph.D., Associate Member, Oklahoma Medical Research Foundation, 825 Northeast Thirteenth Street, Oklahoma City, Oklahoma 73104.

An equal opportunity, affirmative action employer. (NW41)A

(Re-advertisement) EAST MALLING RESEARCH STATION CELL PHYSIOLOGIST

Research post, funded for 33 months, available within group investigating somaclonal variation in strawberries. The successful applicant will be responsible for developing methods for strawberry protoplast culture, design and application of appropriate selection procedures and regeneration of plants.

Qualifications: good honours degree preferably with PhD or at least two years postgraduate research in an appropriate biological discipline. Experience of protoplasts and tissue culture essential, biochemical training useful.

Salary in scale £7,788 — £10,541 per annum.

Further details from Secretary, East Malling Research Station, Maidstone, Kent. ME19 6BJ

East Malling Research Station is an equal opportunity employer. (7144)A

UNIVERSITY OF GLASGOW DEPARTMENT OF VETERINARY PATHOLOGY POSTDOCTORAL RESEARCH ASSISTANT IN VIROLOGY

Applications are invited from post-doctoral scientists to work on a project to develop novel vaccines against equine herpes virus 1 using recombinant DNA techniques.

The successful candidate will have had extensive experience of current techniques in recombinant DNA technology, preferably with a background in virology. This post will be funded for a period of 3 years by the Horserace Betting Levy Board starting in October 1985. The salary will be on the 1A Scale.

Applications, including a curriculum vitae and the names of two referees, should be sent to Dr D. Onions, from whom further information may be obtained, at the Department of Veterinary Pathology, University of Glasgow Veterinary School, Bearsden Road, Bearsden, Glasgow G61 1QH. (7139)A

RU Leiden

The Center for Bio-Pharmaceutical Sciences has a vacancy for a

full professor of pharmacognosy, in particular plant cell biotechnology

vacancy nr 5-106/2407

The Division of Pharmacognosy of the Center conducts research on the phytochemical, analytical and enzymological aspects of the biosynthesis of secondary plant metabolites of a primarily pharmaceutical importance.

This research is intended to provide a basis of the development of new drug manufacturing techniques by means of plant cell biotechnology

The Center for Bio-Pharmaceutical Sciences is a new part of the Faculty of Mathematics and Natural Sciences.

Its primary objective is to conduct multidisciplinary research into the production of drugs, and their disposition and effects in man and animal. In close relation to its research, the Center will also offer a 3 year undergraduate program (M. Sc. Level) as well as a 4 year graduate program (Ph. D. level).

In addition to the Division of Pharmacognosy, the Center contains Divisions of Analytical Chemistry, Biopharmaceutics, Pharmaceutical Technology, Pharmacology, Medicinal Chemistry and Toxicology. The Division of Pharmacognosy is a partner in the Plant Cell Biotechnology Project Group (Biotechnology Delft-Leiden, BDL), together with the Departments of Plant Molecular Biology (Leiden University) and Biochemical Engineering and Applied Enzymology (Delft University of Technology).

The profile of the Center has been specified in a brochure which may be obtained from the Secretary of the Selection Advisory Committee Mr O. H. Postma, P.O. Box 9502, 2300 RA Leiden, The Netherlands. (Phone: 071-148333 extension 4219/4788)

Candidates should have a vast experience relevant to the research program of the Division of Pharmacognosy. They are expected to be able to stimulate research collaboration with other Divisions of the Center as well as with outside partners, including industry.

Proficiency in management of multidisciplinary research is an asset. In addition, candidates should be prepared to engage in the design and teaching of undergraduate and graduate courses. Candidates should also be willing to learn Dutch.

Candidates are invited to send a written application, with full C.V., to the Secretary of the Selection Advisory Committee, Center for Bio-Pharmaceutical Sciences, Gorlaeus Lab., P.O. Box 9502, 2500 RA Leiden, The Netherlands within two months after the publication of this advertisement.

Further information may be obtained from the Committee Chairman, Prof. dr K. R. Lebbenga, Dept of Plant Molecular Biology, Nonnensteeg 3, 2311 VJ Leiden, The Netherlands. (phone: 071-148333 ext 6664 or 6665).

(W2033)A

KUWAIT

University of Kuwait Health Science Centre Faculty of Medicine

Applications are invited for the posts of Chief Technician in the Department of Surgery, Paediatrics, Community Medicine and Behavioural Science, Microbiology (Virology and Immunology). Candidates should have experience as a clinical laboratory technician and hold the FIMLS, or equivalent qualification with 15 years' experience including training. The successful candidates' duties will be of a multi-discipline nature and will be both in laboratory and in the field.

Salary will be in the range KD450 - 512 per month, (KD1 = £2.5, US\$ 3.2 approx.) There is no income tax in Kuwait and currency is transferable without restriction. Free furnished, air-conditioned accommodation is provided, and electricity and water supplied free of charge. Sixty days paid annual leave for each completed year of employment, and annual economy class return air tickets to the country of citizenship or permanent residence are provided for the appointee, spouse and three dependent children. Free medical treatment is available under the State Health Service.

Applications should be submitted to: The Director of Planning and Academic Staff Recruitment, Faculty of Medicine, University of Kuwait Health Science Centre, P.O. Box 24923 Safat, Kuwait, with detailed curriculum vitae in duplicate, recent passport photograph, and the name of three referees, to arrive not later than 30th October, 1985. (W2036)A

MOLECULAR BIOLOGY OF ONCOGENES

IMMUNEX CORPORATION is a Seattle-based biotechnology corporation specializing in the commercial development of lymphokines and immune response modifiers. We wish to expand our group investigating the molecular biology of oncogenes and cloned lymphokine/lymphokine receptor genes. The projects are aimed at increasing our understanding of cell growth regulation in the lymphoid and hematopoietic systems, and require a collaborative approach in a stimulating multidisciplinary environment.

Two positions are available, one for a recent Ph D. graduate, the other requiring post-doctoral experience. The company offers competitive salaries, an equity participation program and a full benefits package.

Application, including CV, list of publications and names and addresses of three referees should be sent to the **Personnel Officer, Immunex Corporation, 51 University Street, Seattle, WA 98101**. Immunex Corporation is an equal opportunity employer.

(NW46)A

IMMUNEX

MEDICAL RESEARCH COUNCIL, Cell Biophysics Unit King's College London

Applications are invited for three three-year post-doctoral appointments:

1. in neurobiology, to work on development in the vertebrate visual system, studying interactions between neurones and glial tissues leading to pattern formation *in vivo*. Experience of cell biological and immunological techniques would be advantageous, (2597)

2. to work in collaboration with muscle and cell motility research groups on the cloning, expression and site-directed mutagenesis of actin. Experience with recombinant DNA techniques would be essential, (2560)

3. on the molecular mechanism of muscle contraction, including the use of fluorescent probes. A background in physiology or biochemistry would be appropriate; (5262)

The appointments will be on the Council's non-clinical salary scale, £7,520 — £15,925 plus £1,233 L.W. and enquiries may be made of Dr J.H. Scholes for position 1 and of Professor R.M. Simmons for positions 2 and 3, (01-836-8851). Applications (including full cv and the names and addresses of two referees, and mentioning which post) should be sent, by 22 August 1985, to: Mr D.M. Drummie, MRC Cell Biophysics Unit, King's College London, 26-29 Drury Lane, London WC2B 5RL. (7135)A

UNIVERSITY OF GLASGOW

DEPARTMENT OF VETERINARY
PATHOLOGY

POSTDOCTORAL RESEARCH ASSISTANT IN MOLECULAR BIOLOGY

Applications are invited from post-doctoral scientists to work on an AFRC funded project to develop retrovirus vectors for gene insertion into embryos.

The successful candidate will have had extensive experience of current techniques in recombinant DNA technology and preferably had experience of work in embryology or virus vectors.

In the first instance this post will be funded for 2 years from October 1985 on the 1A Scale.

Applications, including a curriculum vitae and the names of two referees should be sent to Dr D. Onions, from whom further information may be obtained, at the Department of Veterinary Pathology, University of Glasgow Veterinary School, Bearsden Road, Bearsden, Glasgow G61 1QH. (7137)A

THE MIDDLESEX HOSPITAL

MEDICAL SCHOOL
(University of London)

DEPARTMENT OF MEDICINE RESEARCH ASSISTANT

Applications are invited from science graduates to work on a project investigating the metabolism of vitamin D in man. Postgraduate experience will be an advantage. The research involves the development and clinical application of radioimmunoassays for the metabolites of vitamin D as well as *in vitro* studies of the mode of action of the vitamin. The appointment, funded by the MRC, is tenable until December 1986. Salary up to £10,153 according to age and experience.

Applications, together with telephone numbers and the names of 2 referees, should be sent to: Professor J. L. H. O'Riordan, Department of Medicine, The Middlesex Hospital, Mortimer Street, London W1N 8AA. (7171)A

UNIVERSITY OF EXETER

DEPARTMENT OF BIOLOGICAL
SCIENCES

POST-DOCTORAL RESEARCH ASSISTANT

Applications are invited for the above SERC post from suitably qualified Biochemists or Biologists. Chemists, for a period of 3 years commencing 1 October 1985, or as soon as possible thereafter.

The successful applicant will study the mode of entry of insect steroid hormones (ecdysteroids) into target cells. The project will involve the application of a wide range of biochemical techniques (cell culture, HPLC, affinity chromatography etc) and the chemical synthesis of hormone derivatives.

The starting salary will be within the range £7,520 — £8,450 per annum dependent on age and experience.

Applications including a CV and the names of 2 referees should be sent to Dr L. Dinan, University of Exeter, Exeter, EX4 4QG, from whom further details are available. Closing date 14 August 1985.

(7118)A

UNIVERSITY OF BRITISH COLUMBIA

Department of Botany

Researchers:

POSTDOCTORAL LEVEL and RESEARCH ASSISTANT TECHNICIAN

The project involves the use of the *Agrobacterium tumefaciens* system to introduce foreign genes into plant tissue. Investigation of viral expression, specifically tobacco mosaic virus will also be involved. Techniques of molecular genetics and/or microbial techniques and/or plant tissue culture sought.

To apply, please send curriculum vitae, and names and addresses of referees to: Dr John McPherson, Dept of Botany, #3529 — 6270 University Boulevard, University of British Columbia, Vancouver V6 2B1. (NW47)A

MOLECULAR CARDIOLOGIST

A tenure-track faculty position is available to study the molecular and genetic basis of cardiac muscle development. Experience with recombinant DNA techniques is essential; experience with somatic cell genetics is desirable.

Send Curriculum Vitae, a brief description of research experience and interests, and the names of three references to: Dr Robert Roberts, Chief, Section of Cardiology, Department of Medicine, Baylor College of Medicine, 6535 Fannin St., M.S. F-905, Houston, Texas, 77030. Equal Opportunity Employer. (NW44)A

THE MIDDLESEX
HOSPITAL
MEDICAL SCHOOL
LONDON W1P 6DB
(University of London)

DEPARTMENT OF ANATOMY AND
BIOLOGY AS APPLIED TO
MEDICINE

POST-DOCTORAL
RESEARCH ASSISTANT

Applications are invited for the SRC supported post, tenable from October 1 1985 (or earlier) to work for 3 years on cell contact and movement using advanced fluorescence methods.

Written applications, including the names of two referees, should be sent to Professor D Gingell at the above address. (7126)A

ROYAL POSTGRADUATE
MEDICAL SCHOOL
(University of London)
PAEDIATRICS AND
NEONATAL MEDICINE

Applications are invited for the post

RESEARCH ASSISTANT
in the Jerry Lewis
Muscle Research Centre

Work on a project concerned with the application of recombinant DNA techniques in familial studies of neuromuscular disorders. The project will involve identification of suitable families and collection and processing of samples. Experience of recombinant DNA techniques is essential. The post is funded by the Muscular Dystrophy Association of America and is for one year in the first instance.

Applicants should be graduates with relevant work experience.

Salary will be between £5,316 and £7,520 plus London Allowance, starting point depending on experience.

Application forms may be obtained from the Personnel Office, Royal Postgraduate Medical School, quoting reference number 28/287/N.

Closing Date: 1 August 1985.
(7128)A

UNIVERSITY OF GLASGOW

DEPARTMENT OF VETERINARY
PATHOLOGY
POSTGRADUATE
RESEARCH ASSISTANT
IN VIROLOGY

Applications are invited from postgraduate scientists with degrees in virology, microbiology, or a related discipline, to work on a project aimed at developing novel vaccines to equine herpes virus 1 using recombinant DNA technology.

The successful candidate will have a familiarity with, and an interest in recombinant DNA techniques. Suitably qualified candidates may register for a PhD degree. This post is funded by the Horserace Betting Levy Board for 3 years starting in October 1985 and will be on the 1B salary scale.

Applications, including a curriculum vitae and the names of two referees, should be sent to Dr D Omions, from whom further information may be obtained, at the Department of Veterinary Pathology, University of Glasgow Veterinary School, Bearsden Road, Bearsden, Glasgow G61 1QH. (7138)A

THE SCHOOL OF
PHARMACY
University of London

TOXICOLOGY UNIT,
DEPARTMENT OF
PHARMACOLOGY
LECTURER IN
HISTOPATHOLOGY/
EXPERIMENTAL
PATHOLOGY

required to teach Histology and Comparative Pathology in the BSc course in Toxicology and Pharmacology. Applicants should have strong research interests involving Histology, Pathology or Quantitative Cytochemistry.

Salary in the range £7,520 — £14,925 plus £1,233 pa London Allowance. Further particulars from Dr G Cohen (01-837 7651)

Letters of applications with 2 copies of CV and names of 2 referees to: Personnel Officer, The School of Pharmacy, 29/39 Brunswick Square, London WC1N 1AX, by 31 August 1985, quoting reference GMC/N. (7150)A

INORGANIC CHEMISTRY

Applications are invited for the Chair of Inorganic Chemistry. The person appointed will guide teaching in organic chemistry — initiate research and supervise candidates for higher degrees, participate in the administration of the Department, including perhaps accepting the Headship of the Department, for periods. Inorganic research currently pursued in the Department lies in the fields of bio-organic co-ordination, macrocyclic and organometallic chemistries, and in homogeneous and heterogeneous catalysis.

Closing date 31 August 1985, late applications will be considered.

MICROBIOLOGY

Microbiologists with appropriate experience in one or more of the following fields are required for the posts of Associate Professor/Senior Lecturer and Lecturer in this expanding Department: Environmental Microbiology — Industrial Microbiology — Microbial Metabolism — Plant Virology — Animal Virology. The incumbents will be expected to be active research workers to participate in the teaching of the undergraduate and postgraduate courses given to students in the Faculty of Science and supervise research students. Duties are to be assumed as soon as possible.

Closing date 31 September 1985.

Salary: Professor R35,379; — R40,962; Associate Professor R34,071 — R36,684; Senior Lecturer R23,916 — R31,456; Lecturer R16,257 — £27,648. Benefits include an annual bonus • generous leave • pension • medical aid • remission of fees • sports facilities • clubs • housing subsidy, removal, travel and settling-in allowances (if eligible).

The policy of the University is not to discriminate on the grounds of sex, race, colour or national origin.

For further information contact Mr Geoff Henning, South African Universities Office, Chichester House, 278 High Holborn, London WC1V 7HE. (W2044)A

UNIVERSITY OF
THE WITWATERSRAND

KING'S COLLEGE LONDON
Department of Biophysics

HALF-TIME GRADE 5 TECHNICIAN (Permanent Post)

Enzymologist or physical chemist required for studies on the mechanism of chromatin transcription. The technician will have some responsibility for laboratory organisation. Salary pro-rata on the scale rising from £7,831 — £8,934 pa inclusive (under review).

Teaching Technician Grade 4 (Permanent Post)

Required to run the teaching laboratories. An interesting post concerned with a wide range of courses. Other duties include helping with the animal unit and assisting academic staff with research. Minimum qualification ONC or equivalent, plus at least 7 years relevant experience. Salary on scale rising from £7,356 — £8,274 pa inclusive. (Under review)

Grade 3 Technician (Short term Appointment)

Required for a project funded by the Leukaemia Research Fund to commence as soon as possible until 31st January 1988 on the cloning of genes for eukaryotic gene regulatory proteins. The technician will have some responsibility for organising the laboratory. Experience in recombinant DNA technology is required for this position. Salary on scale rising from £6,649 — £7,575 pa inclusive. (Under review)

Applications for these posts, which should include a C.V. and the names of two referees, should be sent to: Mr. D. Drummie, Administrative Assistant, Biophysics Department, King's College London, 26 Drury Lane, London WC2B 5RL.

Closing date: Friday 9th August 1985.

(7170)A

ONCOGENE SCIENCE INC.

Expanding staff at Long Island, NY research facilities due to advances in

Oncogene and growth factor research

to develop products for the early

detection -- monitoring -- treatment of human cancers.

— Positions Available —

DIRECTOR OF BIOCHEMISTRY

Responsible to direct and coordinate corporate biochemistry program. Ph.D. in Protein Chemistry — purification and sequencing; 8-10 years postdoctoral experience. Strong publication record highly desirable. Will contribute to development of diagnostic and pharmaceutical products.

PROJECT DIRECTOR

Responsible for formatting diagnostic tests for HTLV-III infection and oncogene activation. Test development, pilot and scale-up operations, standardization of appropriate QC procedures. Ph.D. in Immunochemistry. 5-7 years postdoctoral experience in immunoassay, format design, product development.

MOLECULAR BIOLOGIST

To participate in projects aimed at determining the role of oncogenes in human cancer using cDNA cloning in situ hybridization and bacterial expression of antigens. Ph.D. in Molecular Biology, although candidates with Masters degree and appropriate experience will be considered.

Be part of the excitement at OSI.

Send resume and personal data to Scientific Director, Oncogene Science Inc., 222 Station Plaza North, Suite 330. Mineola, NY 11501.

Competitive salary. Liberal benefits. Equity potential.

Equal Opportunity Employer.

(NW31)A

THE UNIVERSITY OF LEEDS

DEPARTMENT OF BIOCHEMISTRY

POSTDOCTORAL RESEARCH FELLOW

Applications are invited for the above post for work in the control of gene expression during Dictyostelium development involving the use of DNA Sequencing, site-specific mutagenesis and the transformation of chimaeric genes into responsive cells.

A good honours degree and a PhD or equivalent experience in a relevant subject are required. Previous experience in recombinant DNA

methodology would be an advantage

Post available from 1 October 1985 for a fixed period of up to three years

Salary within the range £7,520 — £8,920 (under review) on the 1A Range for Research and Analogous Staff, according to age, qualification and experience.

Informal enquiries may be made to Dr B D Hames (tel (0532) 431751 ext 7504).

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number B3/65. Closing date for applications 8 August 1985. (7168)A

UNIVERSITY OF OXFORD

Action Research Professorship of Clinical Neurology

The electors intend to proceed to an election to the Action Research Professorship of Clinical Neurology with effect from 1 October 1987. The stipend of the professorship is at present £26,080, subject to review

Applications (ten copies, or one from overseas candidates), naming three referees but without testimonials, should be received not later than 16 September by the Registrar, University Offices, Wellington Square, Oxford, OX1 2JD, from whom further particulars may be obtained (7163)A

THE UNIVERSITY OF TASMANIA

PATHOLOGY: **POSTDOCTORAL FELLOW** **RESEARCH OFFICER** **(IMMUNOCHEMIST/ BIOCHEMIST)**

The Department of Pathology requires an immunochemist/biochemist to participate in a research programme on the local mechanism of tumour invasion and characterization of the enzymes involved. Applicants should hold a PhD degree and preferably have experience in enzyme biochemistry and immunological techniques. The position is funded by NH and MRC and the initial appointment will be until 3 December 1987. Salary will be within the range \$A22,614 — \$A23,934 pa. For further information about the post contact Professor H K Muller (tel 002-342866 ext 30)

Applications, which should include a cv with details of qualifications and experience, and names and addresses of 3 referees, should be sent to the Registrar, University of Tasmania, Box 252C, G PO Hobart Tasmania 7001, Australia, as soon as possible.

The University is an Equal Opportunity Employer. (W2038)A

UNIVERSITY OF MASSACHUSETTS MEDICAL SCHOOL

DEPARTMENT OF MOLECULAR GENETICS AND MICROBIOLOGY POST-DOCTORAL

RESEARCH FELLOW AND RESEARCH TECHNICIAN Yeast Molecular Genetics/ Secretion

(Ref: BC/133)

Applications are invited for the above positions to study expression of the *S. cerevisiae* dsRNA killer preprotoxin gene, secretion and maturation of its product, and its use for the secretion of foreign proteins in yeast. Post-doctoral applicants should have experience in recombinant DNA techniques and Technician applicants should have a degree or equivalent in biochemistry or a related discipline. Appropriate experience would be an advantage. Post-doctoral salary will be in accord with NIH guidelines and Technician salary will depend on experience and training, both in the range of £15,000 to £19,000.

Further details can be obtained from Dr D.J. Tipper, to whom applications, including a CV and three letters of recommendation, should be sent. Address until November 1st, 1985:

Department of Biochemistry,
University of Oxford,
South Parks Road,
Oxford OX1 3QU (UK)
Telephone 0865 56733 Ext 292

After November 1st, 1985:

Department of Mol. Genetics and Microbiology, U. Mass. Medical School, Worcester, MA 01605, USA
Telephone 617 856 2308. (7172)A

THE UNIVERSITY OF NEW ENGLAND

DEPARTMENT OF ANIMAL SCIENCE

RESEARCH APPOINTMENT

(Genetics of Host-Parasite Relationships)

Equal Opportunity is University Policy

Applications are invited for A Research Appointment (outside funded and subject to annual renewal) in a cooperative research programme between UNE and the CSIRO Divisions of Animal Production and Animal Health. The programme, which was initiated in 1981, is primarily concerned with the genetics of the interaction between sheep and the nematode parasite *Haemonchus contortus*.

The successful applicant will have responsibility for aspects of an investigation into the mechanisms which underlie genetic resistance to *H. contortus* and will work primarily with Dr G D Gray, Professors J S F Barker and R A Leng (UNE) and Drs L R Piper and L F Le Jambre (CSIRO).

Applicants should have a higher degree in physiology, immunology, biochemistry or a related field and have an interest in parasite infections of ruminants.

Informal enquiries may be made directly to Dr Gray in the first instance ISD (61 67 73-2226).

Starting Date: As soon as possible
Salary: \$A18,650 — \$A21,955 depending on qualifications and experience
Position No: 510
Closing Date: 15th August 1985

Applications, including the names and addresses of three referees and stating the position number should be sent to the Staff Officer, University of New England, Armidale N.S.W. 2351, prior to the closing date. Applicants should forward a copy of this advertisement to their referees and ask them to send their reports direct to the Staff Officer, Mr B.G. Turner, before the above closing date. (W2039)A

KINGSTON POLYTECHNIC

FACULTY OF SCIENCE

PRINCIPAL LECTURER IN APPLIED PHYSICS

Applicants for this senior post should be able to demonstrate achievements in an area of Applied Physics in industry, research or education. Areas of particular interest are Applied Optics, Materials, Microelectronics, Instrumentation and Computer Applications, Radiation Science and Acoustics.

The person appointed will be expected to take leadership in the development of collaborative research and have a strong interest in higher education. The post is viewed both as a new blood appointment and as a career opportunity for those with experience.

Salary range £13,773 — (bar) £15,258 — £17,145 including London allowance. Further details and application forms from Personnel Officer, Kingston Polytechnic, Penrhyn Road, Kingston upon Thames KT1 2EE. Tel 01-549-1366 ext 287. Closing date 2 September 1985. (7125)

DURHAM UNIVERSITY

DEPARTMENT OF GEOLOGICAL SCIENCES

Applications are invited for a

SENIOR RESEARCH ASSISTANT

1. Geophysics, tenable for three years, for work on 'Inter-borehole seismic surveys for opencast coal exploration', funded by S.E.R.C. and run jointly by the Departments of Engineering and Geological Sciences. It is concerned with the development of down-hole seismic sources and receivers to determine the continuity of coal seams using

channel waves. Instrument development, fieldwork, data processing and interpretation will be involved. The successful applicant is likely to have a good degree in Physics or Engineering with a PhD or equivalent research experience in a relevant field.

Initial salary £7,520 — £8,920 (under review) on Scale 1A with USS.

Applications (3 copies), naming three academic referees, should be sent by 31 August 1985 to The Registrar, Science Laboratories, South Road, Durham, DH1 3LE, from whom further particulars may be obtained. (7154)A

THE QUEEN'S UNIVERSITY OF BELFAST

MOLECULAR BIOLOGISTS

Northern Ireland Centre for Genetic Engineering

Two Research Officer positions are tenable from 1 October 1985 in this newly established Centre, (Director: Professor S J Martin, Department of Biochemistry) which will provide service/training facilities for the wide range of research projects are underway at the University. Applicants should preferably have substantial practical experience in recombinant DNA techniques, especially involving DNA sequencing and/or oligonucleotide synthesis. The appointees will have the opportunity to participate actively in specific ongoing research projects such as molecular virology, molecular endocrinology, protein engineering or plant genetics. Applicants should preferably have an Honour's Degree in an appropriate molecular biological science or a specific knowledge of synthetic nucleic acid chemistry. A postgraduate degree is not essential.

Salary range: £7,521 — £12,150 per annum with contributory pension rights under USS, initial placing depending on age and experience. Closing date: 10 August 1985. (Please quote Ref. 85/K.)

MOLECULAR BIOLOGIST

Department of Biochemistry

A graduate research assistant is required to investigate the molecular biology of mumps virus. The work will involve the molecular cloning of mumps virus genes and DNA base sequencing and will be part of the Molecular Virology Group led by Professor S J Martin. Candidates should preferably have a good honours degree in an appropriate biological science with a strong interest and motivation for research involving genetic engineering methods. This position is available for a three-year period from 1st October 1985, and is supported by a grant from the Medical Research Council. A suitable person would be encouraged to enrol for a further degree.

Salary range: £6,600 — £8,922 per annum, initial placing depending on age and experience.

Applications including curriculum vitae and the names and addresses of two referees should be sent to the Personnel Officer, at the address below. Closing date: 10th August, 1985. (Please quote ref. 85/P).

RESEARCH ASSISTANT

Department of Oncology

This post, funded by the Ulster Cancer Foundation, is tenable initially for two years commencing as soon as possible. The research involves screening human tumour samples with DNA viral probes. Candidates should preferably have a good honours degree and experience in recombinant DNA technology. A PhD degree would be advantageous although a suitable applicant may enrol for a higher degree.

Salary in the range: £7,521 — £8,922, initial placing depending on age and experience. (Please quote Ref. 85/M).

Applications including a full curriculum vitae and the names and addresses of two referees should be sent to the Personnel Officer, The Queen's University of Belfast, BT7 1NN, Northern Ireland. (7164)A

THE UNITED MEDICAL AND DENTAL SCHOOLS

GUY'S CAMPUS

LABORATORY SCIENTIFIC OFFICER

required in the

DEPARTMENT OF ANATOMY

to join a group working on regeneration within the Central Nervous System. The successful applicant will have considerable experience of neurohistological and immunocytochemical techniques, including all routine HRP developments.

The appointment is for three years. Salary on scale £6,726 — £7,159 per annum plus £1,084 per annum London Weighting.

Application Forms are available from the Staffing Officer, Guy's Hospital Medical School, London SE1 9RT, quoting Ref: G/A/82. (7169)A

UNIVERSITY OF GLASGOW

DEPARTMENT OF CHEMISTRY

POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for a Post-doctoral Research Assistantship, supported by the SERC for work on the Biosynthesis of quinolizidine alkaloids. Candidates should have a strong background in organic synthesis or natural product chemistry. The appointment will be available for two years, starting as soon as possible, at a salary within the range £7,520 — £8,450 per annum (range 1A under review, research staff scale) with USS benefits.

Applications, including a full curriculum vitae and the names of two referees should be sent to Dr D J Robins, Department of Chemistry, University of Glasgow, Glasgow G12 8QQ. (7161)A

DEPARTMENT OF ASTRONOMY University of Leicester

OBSERVATIONS OF PULSATING STARS

Applications are invited for a 3-year postdoctoral position tenable from October 1985. The research will involve optical and near infrared photometry of pulsating stars, particularly RR Lyrae variables, and measurement of their radial velocity curves. The aim being to determine radii and absolute magnitudes and thus a calibration of the distance scale. Previous experience of IR or optical photometry or optical spectroscopy would be an asset. Starting salary is in the range £7,520—£9,390, plus USS benefits, depending on age and experience.

Applicants should send a curriculum vitae with a list of publications and should arrange for two referees to write in their support. Applications and references should be received by 31 August and should be sent to: Dr. R.F. Jameson, Astronomy Department, The University, Leicester, LE1 7RH, to whom any further enquiries should also be directed.

Quasars and Active Galactic Nuclei

An SERC-supported postdoctoral research post will be available from October 1985 for work on the development of theoretical models of active galactic nuclei. The post is tenable for up to three years at a starting salary (under review) of up to £9,390 p.a., plus USS benefits, depending on qualifications and experience.

Applicants should send a curriculum vitae and list of publications, together with any other relevant information, and should arrange for two referees to write in their support. Applications and references should be received as soon as possible and not later than 31 August 1985. They should be addressed to: Dr. D.J. Raine, Astronomy Department, The University, Leicester, LE1 7RH, to whom any further enquiries should also be directed. (7134)A

THE UNIVERSITY OF SYDNEY CHAIR OF RESTORATIVE DENTISTRY Reference no 11/04

Applications are invited for the Chair of Restorative Dentistry which became vacant following the retirement of Professor J S Lyell, who held the Chair with the title of Operative Dentistry. The Chair is at present located in the Department of Operative Dentistry but the Faculty is currently considering a reconstruction of its departments and its clinical teaching.

The main teaching and research areas are operative dentistry, crown and bridgework, endodontics and dental materials science.

Applicants should have advanced clinical experience in one or more of these areas and hold a dental qualification which entitles them to practise dentistry in New South Wales.

Salary will be at the rate of \$A52,026 per annum and there is at present a clinical loading.

The University reserves the right not to proceed with any appointment for financial or other reasons.

Applications in duplicate, quoting reference no, including curriculum vitae, list of publications, and the names and addresses of three referees, to the Registrar, University of Sydney, NSW 2006, Australia, by 24 May 1985

Further information should be obtained from Secretary General, Association of Commonwealth Universities (Apts), 36 Gordon Square, London WC1H 0PF. (W2042)A

UNIVERSITY OF EDINBURGH

DEPARTMENT OF BACTERIOLOGY

(in collaboration with the Moredun Research Institute)

Applications are invited for a

POST-DOCTORAL RESEARCH ASSISTANT

to assist Dr I R Poxton and J A Spence (Moredun Research Institute) in a project funded by the Wellcome Trust entitled "A Study of Gram-negative Bacteria and Spirochaetes in Developing Broken Mouth of Sheep". This will involve the isolation and identification of anaerobic bacteria and spirochaetes from the mouths of diseased and healthy sheep, immunochemical characterisation of the bacteria and measurement of locally-produced and systemic antibodies.

Experience in anaerobic culture techniques is desirable and an interest in immunology or immunochemistry would be an advantage but is not essential. The position is for three years. Salary scale (Research Range 1A) £7,520—£8,920 (under review).

Further details from and applications (including the names of two academic referees), (four copies) to Dr Ian R Poxton, Bacteriology Department, University of Edinburgh Medical School, Teviot Place, Edinburgh, EH8 9AG Closing date for applications 31 August 1985.

Please quote reference 5264. (7159)A

THE UNIVERSITY OF MELBOURNE LECTURER (Continuing or Limited Tenure) in the

DEPARTMENT OF PHARMACOLOGY

Applications are invited for the above position. The successful applicant will be expected to have a PhD or equivalent qualification plus teaching and/or research experience in toxicology, but a well qualified pharmacologist who is prepared to embark on a primary commitment to toxicology could be considered. The appointee will be expected to carry out research, teach and otherwise practise as a toxicologist, but will also teach in other selected areas of pharmacology to medical, dental and science undergraduates

Further enquiries may be directed to Professor M J Rand in the University, telephone (03) 344 5673.

The commencement date for this position is in the period November 1985 to February 1986. Salary within the range \$A23,236—\$A34,467 per annum.

Further printed information regarding details of application procedure and conditions of appointment is available from the Appointments Officer (Academic), University of Melbourne, Parkville, Victoria 3052, Australia, or the Secretary General, Association of Commonwealth Universities (Apts), 36 Gordon Square, London WC1H 0PF.

Applications, in duplicate, including names and addresses of at least three referees and quoting position number 534 0020 should be addressed to the Staff Officer, University of Melbourne, and close on 30 September 1985.

Equal opportunity in employment is the policy of the University of Melbourne. Selection is based on merit and all applications will be assessed regardless of sex, race, ethnicity or disability.

Applications from both men and women are invited for all vacancies. (W2043)A

UNIVERSITY OF CAMBRIDGE Department of Physics POSTDOCTORAL RESEARCH ASSISTANTS

Applications are invited for two posts for work on polymer and colloid physics. The project will focus on interactions between polymers and surfactants at interfaces which will be studied using direct force measurement techniques and other complementary methods. Applicants should have a PhD in Physics or Chemistry and preferably experience in colloid/interface science. The posts are tenable up to two years. Salary within the range £7,520—£9,860 pa.

Applications including cv and names of two referees should be sent to The Secretary, Cavendish Laboratory, Madingley Road, Cambridge CB3 0HE. (7165)A

MONASH UNIVERSITY CENTRE FOR EARLY HUMAN DEVELOPMENT RESEARCH ENDOCRINOLOGIST Monash-IVF Programme

Duties include: (1) Supervision of routine IVF hormone assays, (2) Development of experimental techniques to expand the Endocrine research component of this IVF programme and (3) Liaison with clinical colleagues and motivation of junior staff within the IVF programme. Appointee would have basic endocrine research facilities and possible appointment as Research Fellow in the Centre for Early Human Development and Department of Obstetrics and Gynaecology. Applicants must have a PhD and good research record in basic and laboratory endocrinology. Salary: \$A22,614—\$A34,467 pa

Enquiries to Dr A Trouson, Centre for Early Human Development, Queen Victoria Medical Centre, 172 Lonsdale Street Melbourne, Australia 3000.

Applications including Ref no 32962, curriculum vitae and referees to the Registrar, Monash University, Clayton, Vic 3168 Australia by 31/8/85

An equal opportunity employer. (W2045)A

THE ANIMAL VIRUS RESEARCH INSTITUTE SCIENTIFIC OFFICER

Applications are invited for the post of Scientific Officer to work in a group investigating the molecular biology of African Swine Fever virus. This virus contains a complex double-stranded DNA genome. The project involves analysis of the structure and function of the viral genome, using recombinant DNA methods and associated techniques. Collaboration with other groups within the Institute studying the immunology and pathogenicity of the virus is involved. The successful candidate will have a First or upper second class honours degree in a biological science, experience in molecular biology techniques is desirable.

Salary scale. £6,190—£8,561.

22 days annual holiday, non-contributory superannuation and sickness benefit schemes. A house may be available for a suitable, married applicant.

Applications to include curriculum vitae and the names of two referees to be sent as soon as possible to the Secretary, The Animal Virus Research Institute, Ash Road Pirbright, Woking, Surrey GU24 0NF. Tel: 0483 232441

The Animal Virus Research Institute is an Equal Opportunity Employer. (7156)A

THE UNIVERSITY OF LEEDS

DEPARTMENT OF PHYSIOLOGY POSTDOCTORAL RESEARCH FELLOW

Applications are invited for the above post for work on the neural control of cilia in *Lymnaea* involving the use of electron-microscopy and electrophysiological techniques.

A good honours degree in Physiology, Zoology or Anatomy and a PhD or equivalent experience in a relevant subject are required. Candidates should also have postgraduate experience of ultrastructural techniques.

Post available from 1 October 1985 for a fixed period of up to three years.

Salary within the range £7,520 — £8,450 (under review) on the 1A range for Research and Analogous staff, according to age, qualification and experience.

Informal enquiries may be made to Dr W Winlow (tel (0532) 431751 ext 7443 or 7165).

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT quoting reference number 94/14. Closing date for applications 16 August 1985. (7167)A

NUTRITIONIST

The Medical Research Council

wishes to appoint a Nutritionist to take part in the range of dietary studies undertaken by the Environmental Epidemiology Unit. The Unit uses epidemiological methods to investigate the influence of the environment in the aetiology of chronic disease. The main programmes of research are dietary and industrial. The Unit is associated with the Faculty of Medicine, Southampton University and is sited at Southampton General Hospital.

The appointment will be for three years in the first instance, to the MRC scientific staff on a salary scale comparable to University academic salaries; and at a point appropriate to age and experience.

Further information and application details may be obtained from the Director, MRC Environmental Epidemiology Unit, Southampton General Hospital, Southampton SO9 4XY

Closing date for applications August 30th. (7114)A

MEDICAL RESEARCH COUNCIL

Laboratory of Molecular Biology, Cambridge

ORGANIC CHEMIST

Applications are invited from post-doctoral scientists with a strongly developed interest in bioorganic chemistry to join a group working in the peptide and oligonucleotide field. Previous experience in peptide synthesis would be an advantage but is not essential.

L'UNIVERSITE DE LAUSANNE

ouvre une inscription en vue de pourvoir, dès le 1er septembre 1986, un poste de

PROFESSOR ASSOCIE

rattaché à l'Institut de Zoologie et d'Ecologie animale (IZEA) de la Faculté des sciences.

Il s'agit d'un poste à plein temps, comportant de l'enseignement (écologie quantitative, génétique des populations et spéciations) et de la recherche (relations phylétiques et écologie des mammifères).

Les candidatures (curriculum vitae, liste des publications, tirés à part des publications les plus significatives) doivent parvenir avant le 30 septembre 1985 au professeur Bernard TESTA, doyen de la Faculté des sciences, Collège préposé, 1015 Lausanne-Suisse. (W1993)A

SOUTH MANCHESTER HEALTH AUTHORITY

Christie Hospital and Holt Radium Institute Paterson Laboratories POST-DOCTORAL RESEARCH FELLOW

A post-doctoral position is available in the Department of Radiation Biology for a cell biologist with an interest in endothelium and with experience in culture techniques required for the investigation of long-term cytotoxic injury in bone marrow

Initial salary will be in the range £8,450 to £11,205 per annum (under review), depending upon age and experience and the initial term of the appointment will be 3 years.

Applications, together with cv, and the names of 2 academic referees, should be forwarded to Dr J H Hendry, Department of Radiation Biology, Paterson Laboratories, Christie Hospital & Holt Radium Institute, Wilmslow Road, Manchester M20 9BX. (7162)A

The post is available for 3 years from September 1st or as soon as possible thereafter. Salary in the range £8,920 to £14,925 pa. Further information from Dr R C Sheppard (Cambridge) (0223) 248011).

Applications — including a full CV, a short statement on relevant experience and the names of two professional referees — should be sent by (August 8th 1985), quoting reference RS/85 to: The Assistant Director, MRC Laboratory of Molecular Biology, Hills Road, Cambridge, CB2 2QH. (7166)A

UNIVERSITY OF BRISTOL LONG ASHTON RESEARCH STATION HEAD OF WEED RESEARCH DIVISION

An experienced scientist is required to lead and to manage the Weed Research Division, which is to be established at Long Ashton Research Station. The Division will have national responsibility for fundamental, strategic and applied research on weeds and weed control and associated areas of vegetation management. The Division will need to collaborate extensively with others both internally and externally.

While the minimum qualification is a good Honours Degree or equivalent, no applicant is likely to be appointed who has not been awarded a Higher Degree and gained a well established reputation in relevant scientific disciplines. The post requires an understanding of the administration of research and the experience and personality to ensure the respect of expert staff and to provide them leadership.

Appointment is in Grade 6 (£17,000 to £22,926 per annum) Non-contributory superannuation scheme.

Further particulars from: The Secretary, Long Ashton Research Station, Long Ashton, Bristol, BS18 9AF. Written applications, with a CV and the names of three referees must be received by Thursday, 1st August, 1985. (7145)A

POST-DOCTORAL POSITION

available after 1 October

Cell biology-physiology-biochemistry laboratory studying isolated cardiac membrane channel proteins seeks

IMMUNOLOGIST OR PROTEIN BIOCHEMIST

with immunological experience for immunofluorescence and immunoelectron microscopic investigations. Applicant should have doctorate and experience with poly- and monoclonal antibody techniques.

Send curriculum vitae, description of research interests, references to: Dr. Ernest Page, Department of Medicine, BH Box 137, The University of Chicago, 5841 South Maryland Avenue, Chicago, Illinois 60637. Equal Opportunity/Affirmative Action Employer. (NW45)A

UNIVERSITY OF WALES COLLEGE OF MEDICINE DEPARTMENT OF MEDICINE PhD SCHOLARSHIP

available in the above Department as soon as possible to work in the general field of neuroendocrinology/neurobiology. The areas include the application of radioimmunoassay and HPLC and neurone culture to the study of hypothalamic and other brain neuropeptides. Work also includes the study of the applications of neurotransmitters and neuro-modulators to the control of endocrine function in general and neuroendocrine function in particular. Other methodology involves the measurement of catecholamines by HPLC with electrochemical detection.

Applications, in the form of a curriculum vitae with the names and addresses of two referees and quoting Ref No M6/99 should be submitted to the Registrar and Secretary, Personnel Office, University of Wales College of Medicine, Heath Park, Cardiff, CF4 4XN by 9th August, 1985.

Further information available from Dr Maurice Scanlon (Tel No 0222/755944 Ext 2182) (7148)A

UNIVERSITY OF OXFORD DEPARTMENT OF BIOCHEMISTRY Genetics Laboratory POSTDOCTORAL RESEARCH ASSOCIATE — GRADE 1A (Ref: G/R/132)

A postdoctoral research assistant is needed to organise a DNA bank, to assist in an associated cell bank, and to undertake restriction enzyme and allied analyses of families relevant to Duchenne's muscular dystrophy. All these techniques are well established in the laboratory. The position, funded by the Muscular Dystrophy Group, will be for one year in the first instance, but is expected to continue for at least a further year. Graduates with relevant experience will be considered. Exceptional candidates would be considered for part-time work.

Salary on the scale (or pro rata to) £7,520 — £9,860 pa (under review) depending on age and experience.

Applications, including the names and addresses of two referees should be sent, as soon as possible, to: The Administrator, Department of Biochemistry, South Parks Road, Oxford. OX1 3QU (7124)A

Vaccine Research & Production
Laboratory

RESEARCH ASSISTANT

Required in the Vaccine Research and Production Laboratory at the Centre for Applied Microbiology and Research, Porton Down. Duties involve the characterization of monoclonal antibodies for potential use in the diagnosis and study of the antigenic structure of human cytomegalovirus, to be carried out in association with the Department of Medical Microbiology, St Georges Hospital, London. The appointment is to run for one year with effect from October 1985.

Applicants should have obtained, or expect to obtain, an honours degree in an appropriate subject, must be under the age of 32 and have studies or worked continuously for the past three years in a university or hospital in the United Kingdom

Salary in the range £6,559-£8,725

National Health Service terms and conditions apply

Application forms from the Personnel Officer, PHLS Centre for Applied Microbiology & Research, Porton Down, Salisbury, Wilts SP4 0JG to be returned by 15th August 1985.

Please quote Reference No 82 when applying. (7142)A

**THE UNIVERSITY OF
LEEDS**

DEPARTMENT OF BIOCHEMISTRY

**PREDOCTORAL
RESEARCH ASSISTANT**

Applications are invited as soon as possible for the above post in the MRC Membrane Peptidase Research Group for work on studies of a panel of monoclonal antibodies recognising antigens in renal and intestinal brush border membranes as well as in generating new hybridomas. The techniques include those of mammalian cell culture, immunocytochemistry and those involved in characterizing the antigens recognised. Candidates should have a degree in an appropriate subject and some relevant laboratory experience.

The post is available from 1 September 1985 for a fixed period of up to thirteen months

Salary on the IB Range for Research and Analogous Staff (£6,600 — £8,920 (under review), according to age, qualifications and experience.

Informal enquiries may be made to Dr A J Kenny (tel (0532) 431751 ext 7438).

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference no 83/63. Closing date for applications 1 August 1985. (7153)A

LA TROBE UNIVERSITY
Melbourne, Australia

**School of Physical Sciences
LECTURER IN GEOLOGY
(GEOLOGIST/
GEOPHYSICIST)
(TENURABLE)**

Applications are sought for a tenurable lectureship in the Department of Geology. Applicants should have a PhD or equivalent applied experience in either geology or geophysics and expertise in the application of geophysics to geological problems. Possible areas of research interest could include petroleum or mineral exploration, seismic stratigraphy, geology and geophysics of the ocean basins or structure and geophysics of the continental crust. The successful applicant will be expected to establish a geophysics program for senior undergraduates and to carry out research and supervision of post-graduate students in the field of interest.

Salary: \$A26,236 — \$A34,467.

Applications, marked 'Confidential' and quoting reference number A0/024/013, close with the Staff Officer, La Trobe University, Bundoora, Victoria, Australia 3083, on 16 August 1985. Candidates in UK or Europe should also send a copy of their application to the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, from whom further information is available (W2034)A

**CONFERENCES &
COURSES**

**UNIVERSITY OF READING
DEPARTMENT OF SOIL SCIENCE
MSc COURSE IN
SOIL SCIENCE: SOIL
WATER MANAGEMENT**

Places are available on this new course starting in October 1985. It lasts one or two years depending on whether project work is undertaken in Reading or overseas.

The purpose of the course is to provide training in the efficient management of water in soils, especially in arid and semi-arid regions. Specialized courses are provided in soil physics, the behaviour of water in soils, agricultural meteorology, water relations of crops, and the management of soil water for crop production in rain-fed agriculture. During the course, emphasis will be placed on instrumentation and measurement techniques leading to the effective management of water. Project work can be undertaken overseas where appropriate arrangements can be made.

Applications are invited from graduates with a science background. No research council studentships can be offered for entry in October 1985.

Enquiries to the Secretary, Department of Soil Science, University of Reading, London Road, Reading RG1 5AQ. (7173)C

ENGINEERING**

**Applications are invited for a post of
POSTDOCTORAL
RESEARCH FELLOW**

to work on a protein engineering project to study membrane anchor regions in hybrid enzymes. This work will involve recombinant DNA methods (including the use of oligonucleotides), enzymological and immunological techniques.

Applicants should have a PhD in Biochemistry, Genetics or a related field preferably with experience in membrane protein biochemistry and experience in, or willingness to learn recombinant DNA techniques.

Post available from 1 October 1985 for a fixed period of up to two years.

Salary within the range £7,520 — £9,860 (under review) on the 1A Range for Research and Analogous Staff according to age, qualifications and experience.

Informal enquiries may be made to Dr M J McPherson (tel (0532) 431751 ext 402).

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number 201/5. Closing date for applications 8 August 1985. (7122)A

FELLOWSHIPS

**UNIVERSITY OF
EDINBURGH**

**DEPARTMENT OF BIOCHEMISTRY
SERC POSTDOCTORAL
FELLOWSHIP**

Applications are invited for a SERC supported postdoctoral fellowship to work on refinement of the molecular structure of collagen and analysis of interactions of collagen with other molecules. Experimental work will involve use of synchrotron radiation, molecular graphics and computing. New specimen preparation procedures are being developed and a low-temperature device constructed. The department is well equipped for the relevant experimental work.

The position is for three years starting salary on range £7,520 — £8,920 (under review), and is available immediately.

Please apply to Professor J. Miller, Department of Biochemistry, University of Edinburgh Medical School, Hugh Robson Building, George Square, Edinburgh, EH8 9XD, enclosing curriculum vitae and the names and addresses of two referees.

FELLOWSHIPS

UNIVERSITY OF NOTTINGHAM MEDICAL SCHOOL

Department of Biochemistry POST-DOCTORAL FELLOW

Applications are invited for a research fellowship financed by the British Heart Foundation for a study of phosphoinositide metabolism and the molecular mechanisms mediating the responses of cardiac muscarinic receptors. The fellowship is available for two years initially from 1 October, 1985 at a starting salary of £7,980 or £8,450 depending on age and experience. Membership of USS included.

Applicants should send curriculum vitae and the names of two referees to Professor J N Hawthorne, Department of Biochemistry, Medical School, Queen's Medical Centre, Nottingham NG7 2UH, from whom further details may be obtained (telephone: 0602-700111 ext 3488). Closing date 31st August, 1985. (7115)E

COLEG PRIFYSGOL GOGLEDD CYMRU University College of North Wales, Bangor

DEPARTMENT OF BIOCHEMISTRY AND SOIL SCIENCE POSTDOCTORAL FELLOWSHIP

Salary:— £7,520 — £9,390 per annum

Applications are invited for the above position to study the control of sugar accumulation in sugar beet storage tissue. The work will involve use of the micropressure probe to measure the pressure dependence of ion fluxes as well as more conventional biochemical and physiological techniques.

The post is funded by the AFRC starting on the 1st October, 1985, until end of February 1987, and the successful applicant should have a PhD with a strong background in plant physiology or biochemistry and an interest in biophysical methods.

Applications (two copies), giving details of age, education and experience together with the names and addresses of two referees should be sent to the Personnel Office, University College of North Wales, Bangor, Gwynedd LL57 2DG, from whom further particulars may be obtained. Informal enquiries may be made to either Professor R G Wyn Jones or Dr A D Tomos, Department of Biochemistry and Soil Science. Telephone Bangor (0248) 351151, Extension 359/304.

Closing date for applications: 1st August, 1985. (7117)E

IMPERIAL CANCER RESEARCH FUND RESEARCH FELLOWSHIP

A post-doctoral, three year appointment is available in our Cellular Pharmacology and Antitumour Chemistry Laboratory, to work with Dr A Creighton on projects involving tumour therapy with antibody targeted radionuclides.

Salary range £10,285 to £12,570, entry according to qualifications and experience. Further details are available from Ms S M Hurley, Imperial Cancer Research Fund, Lincoln's Inn Fields, London, WC2A 3PX, telephone 01 242 0200 ext 305 quoting reference: 93/85. (7147)E

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE (University of London)

DEPARTMENT OF BIOCHEMISTRY AND CHEMISTRY JUNIOR RESEARCH FELLOWSHIP

Applications are invited from graduates on students obtaining a good honours degree in Biochemistry or related subjects for a three year Junior Research Fellowship, starting on 1 October 1985. The successful candidate will register for a higher degree in the University of London. The project concerns the mechanisms of polyphosphoinositide metabolism and arachidonic acid release in endocrine cells. The conditions of employment and salary are similar to the SERC/MRC studentships.

A curriculum vitae and the names of two academic referees should be sent to Professor B.A. Cooke, Department of Biochemistry and Chemistry, Royal Free Hospital School of Medicine, Rowland Hill Street, London, NW3 2PF. Telephone 01-794-0500 extension 4202.

(7116)E

UNIVERSITY COLLEGE DUBLIN

Departments of Zoology and Botany

POSTDOCTORAL FELLOWSHIP

Applications are invited for a post-doctoral fellowship (IR£9,000 — £9,500 inclusive of PRSI) supported by the NBST to investigate chemical markers for crop resistance to insect attack in association with Drs M F Ryan and G Wilson. A PhD is desirable in plant cell culture technology and/or use of polyclonal/monoclonal antibodies.

Send curriculum vitae with the names of two referees to: Dr Michael F Ryan, Department of Zoology, University College Dublin, Belfield, Dublin, 4, by 10th August, 1985. (7174)E

EMBO European Molecular Biology Organization LONG TERM FELLOWSHIPS IN MOLECULAR BIOLOGY Autumn 1985 — Awards

Next deadline: 15 August 1985

EMBO long term post-doctoral fellowships are awarded to promote the development of molecular biology and allied research in Europe and Israel. To be eligible a candidate must hold a doctorate degree and the exchange must involve a laboratory in Western Europe or Israel. EMBO fellowships are not, however, awarded for exchanges between laboratories within any one country. Long term fellowships are awarded initially for one year, but depending on a review of progress, they may be renewed for a second year. In cases of exceptional scientific merit renewal for a third year is possible. The fellowship comprises a return travel allowance for the fellow and any dependents and a stipend and dependents' allowance.

Since the selection procedure may include an interview, candidates are requested to respect the deadline for complete applications which is 15 August 1985. Successful candidates will be notified of their awards immediately after the meeting of the selection committee, which is on 21 October 1985.

Application forms and further details may be obtained from Dr. J. Tooze, Executive Secretary, European Molecular Biology Organization, Postfach 1022.40, 69 Heidelberg 1, F. R. Germany. (W1893)E

ESO FELLOWSHIPS 1986 — 1987

The European Southern Observatory (ESO) intends to award up to six fellowships tenable in the ESO Scientific-Technical Center which is located in Garching near Munich.

The main areas of activity are:

- to carry out a program of development of auxiliary instrumentation for the La Silla telescopes;
- to develop plans for future telescopes involving new technology;
- to make studies in observational and theoretical astrophysics so that the observing facilities may be used in an optimal way;
- to provide data reduction facilities to users of the ESO instruments;
- to provide photographic facilities for atlases of the southern sky;
- to foster cooperation in astronomy and astrophysics in Europe.

In addition there is the possibility of participating in the activities of the European Coordinating Facility of the Space Telescope (ST-ECF) which has recently been established at ESO.

Most of the scientists in the Center come from the Member States of ESO, but several are from other countries. The Member States of ESO are: Belgium, Denmark, the Federal Republic of Germany, France, Italy, the Netherlands, Sweden, and Switzerland. In addition to regular staff members, the Center comprises visiting scientists and postdoctoral fellows.

ESO facilities include the La Silla Observatory in Chile with its seven telescopes in the range of 0.9 to 3.6m, as well as a 1m Schmidt and some smaller instruments. In Garching, extensive measuring, image processing and computing facilities are available.

Applicants normally should have a doctorate. The monthly basic salary will be not less than DM 3635 to which are added 7% for pension purposes and a non resident allowance of 9 — 12% if applicable. The fellowships are granted for one year, with normally renewal for a second year. Applications should be submitted to ESO not later than 15 October 1985. Applicants will be notified around 15 November 1985. The ESO Fellowship Application form should be used and be accompanied by a list of publications. In addition, three letters of recommendation should be obtained from persons familiar with the scientific work of the applicant. These letters should reach ESO not later than 15 October 1985.

Enquiries, requests for application forms and applications should be addressed to:

European Southern Observatory
Fellowship Program
Karl-Schwarzschild-Strasse 2

**POST-GRADUATE STUDENTSHIP IN
BIOCHEMICAL/QUANTITATIVE GENETICS**

A post-graduate studentship has been awarded to investigate the genetic basis of variation in cholesterol and fat content of eggs. The student would join the Genetics Group at the above Centre. This Group consists of four scientists, their staff and students working on a broad range of projects covering molecular, developmental, biochemical and quantitative genetics of poultry and mice. The successful candidate would register for a Ph.D. degree in the Department of Genetics, Edinburgh University, with which the Genetics Group has close links.

The Scholarship (£2,700 p.a.) has been awarded by the British Egg Marketing Board's Research and Education Trust and is tenable for 3 years from 1st October 1985. Applicants should have, or expect to have, a first or upper second class honours degree in a relevant biological science. Application forms are available from the Assistant Secretary at the above address.

Further information can be obtained from Dr Jim McKay or Dr G Bulfield (031-440-2726). Applications should be returned by 9th August 1985. (7158)F

Tenable for 3 years from October 1985 to work on SERC project in optical dating, primarily for sediments on palaeolithic sites. Applicants need to have a good honours degree in physics plus PhD or other experience comprising research in TL and ESR dating including techniques for annual dose evaluation. Starting salary in the range £7,520—£9,390 according to age and experience.

Applications naming three referees, before August 12 to administrative secretary, 6 Keble Road, Oxford OX1 3QJ. (7176)P

**UNIVERSITY OF BRISTOL
Long Ashton Research Station
AGRICULTURAL AND
FOOD RESEARCH
COUNCIL STUDENTSHIP**

Applications are invited for a research Studentship on the influence of endogenous hormone concentrations and applied plant growth regulators on resistance to fungal infections in bean.

Candidates should normally be under 30 years of age on 1st October 1985 and should have been ordinarily resident in the United Kingdom throughout the period of 3 years immediately preceding the date of application for a studentship. Applicants should have a first or upper second class degree in a physical science, with knowledge of plant chemistry, physiology and pathology. The successful applicant will be expected to register for a high degree in the University of Bristol.

Application forms and further particulars can be obtained from the Secretary, Long Ashton Research Station, Long Ashton, Bristol, BS40 9AF.

The closing date for receipt of completed application forms is 1st August, 1985. (7143)F

If you have to say FPLC you are half way there ...

... because PepRPC™ and ProRPC™ from Pharmacia are the state of the art in reversed phase chromatography media for separating and recovering biological molecules.

Pharmacia reversed phase chromatography columns have been specially designed for high resolution chromatography of peptides, polypeptides and proteins, forming a natural complement to ion exchange

chromatography and chromatofocusing when separating biomolecules using the Pharmacia FPLC System.

Pharmacia media PepRPC and ProRPC provide you with new and unique reversed phase selectivities (C_2/C_{18} and C_1/C_8) optimised for peptides and proteins. Excellent control over the new synthesis ensures reproducibility from batch to batch.

... so go all the way.

The Pharmacia RPC media are prepacked in borosilicate glass columns with optimised lengths to utilize a range of reversed phase separation techniques for high resolution and high recoveries of both large and small polypeptides.

- Controlled synthesis for batch to batch reproducibility
- High recoveries of peptides and polypeptides
- High resolution of hydrophobic fragments
- Optimised bonded phase composition

FPLC from Pharmacia
goes beyond HPLC with biocompatibility,

INTERNATIONAL WEEKLY JOURNAL OF SCIENCE

Vol 316 No 6026 25-31 July 1985 £1.80

TWENTY-FIVE
YEARS OF
LASERS

The collector that can't lose a drop, doesn't waste your time and won't cost a fortune.

You'll find more LKB fraction collectors at work in laboratories throughout the world than any other.

The new HeliRac™ Fraction Collector from LKB

This new compact guarantees that no tube will ever change until the drop has been collected. So you won't waste your sample or your time. And the world's fastest time for tube change gives you perfect collection in any mode you choose: time, volume or drop. You'll also get simplified waste collection, with zero dead volume and hence no contamination. So if you want reliability, HeliRac's got it. And if you want to save time, it's got every feature to automate your entire collection.

With more intelligence than many larger instruments, HeliRac is so simple to program and so easy to use. Let it run your system or be its slave. You'll get 6 time windows for optimal collection.

4 memories for program storage and an escape key to speed up parameter changes. That's the kind of flexibility you've always wanted in a collector so small and with a price that's so sensible.

When you've seen it at work in your own laboratory, you'll know why the performance and value of HeliRac just can't be matched. Try it today and you'll know for yourself.

NOW FILL THIS IN TODAY

- ☐ Send me the facts.
- ☐ Show me how HeliRac can help my laboratory.
- ☐ Send me a quotation.

Circle No. 17 on Reader Service Card.

Hoefer has expanded the Mighty Small line

Hoefer's Mighty Small I has become the laboratory standard for doing electrophoresis in the small gel format. Now Hoefer is introducing Mighty Small II, and to complete the system, Mighty Small Transphor, Cast- ing Stand, and Power Supplies.

- **Mighty Small II** is Cool and Fast: It can run two mini-gels, 8 x 10 cm, in 45 minutes. Two mini-gels are produced in two gel sandwiches, held back to back, in a

double-sided pod. The pod consists of two discretely separate upper buffer chambers and a serpentine coolant chamber between. *Cooling is the key feature of the Mighty Small design.* The back plate of each gel sandwich is in contact with the upper buffer and is made of sturdy alumina. Alumina is an excellent heat conductor, 40 times faster than a comparable thickness of glass. It rapidly conducts joule heat away from the gel sandwich into the buffer. A serpentine coolant chamber, permanently sealed between the two buffer chambers, assures further heat dissipation. This excellent cooling system means you can get flat, side by side sample lanes with no smile in 45 minutes.

Reader Service No. 51

- **The Mighty Small Multiple Gel Caster** enables you to cast 10 gels at a time, 8 x 10 cm, gradient or native. You can pour batches of gels ahead of time,

probably a week's supply.

Reader Service No. 52

- **The Mighty Small Transphor** can transfer proteins from four small gels (up to 9 x 10 cm) at once, to either nylon membranes or nitrocellulose, in as little as 30 minutes. It comes complete with four

glass-filled polycarbonate cassettes. A serpentine cooling channel milled into the base and covered with alumina assures excellent cooling. Under standard transfer conditions the temperature variation will be less than 5°C. Platinum wire, 155 cm of it, strung in 14 opposing strands 1½ cm apart establishes a uniform electrical field. Because of its small size, it is possible to use a standard electrophoresis power supply—we recommend the Hoefer PS 500X. Mighty Small Transphor requires only a small amount of buffer, about one liter, another important cost-saving factor.

Reader Service No. 53

- If you want to run small gels, 100 mm wide x 80 mm high, the **Mighty Small I** does the job fast and right. You can run a 10% gel at 200 constant volts in only 42 minutes. The gel sandwich is the core of the design. Its alumina back interfaces with the buffer pod to insure even heat distribution across the gel surface. The result: flat,

side-by-side bands.

Reader Service No. 54

- Hoefer introduces a new line of **transfer membranes** for all blotting techniques: a pure grade of nitrocellulose to insure faithful replicas and minimal background staining, and high binding capacity Nylon 66 membranes. You have a wide choice of shapes and pore sizes.

Reader Service No. 55

- **The PS 250 power supply** is a work-horse for the electrophoresis lab. It can produce 0-250V; 0-2.5A, adjustable in

both voltage and current. It has two digital panel meters and a 7 hour timer. You can run six Mighty Small II units at one time and monitor each separately. For transfer work the PS 250 provides ample current for several small or large transfer units. *We recommend running transfers in constant current to eliminate overheating.*

Reader Service No. 56

- **The PS 500X**

is the standard power supply for small gel electrophoresis. It can produce 0-500V, 0-400mA; adjustable in voltage and current; automatic crossover from current to voltage. You can run two Mighty Small II units at one time or two Mighty Small Transphor units.

The PS 500X is portable (only 8 lbs.) and compact (4" x 8" x 12").

ONCOGENE SCIENCE, INC.

Introduces...

OSI™ DNA Probes to:

• Human Oncogenes

- c-H-ras (cDNA)
- c-K-ras (genomic)
- c-N-ras (cDNA)
- c-abl (genomic)
- c-fes (genomic)
- c-sis (genomic)
- c-raf (cDNA)
- c-fms (genomic)

• Chromosomal Breakpoints

- bcr probe (Ph' translocation)

OSI™ DNA probes are provided in pSP vectors designed for use in both nick-translation and RNA transcription labelling. Each vial contains 2.5 µg of DNA. Oncogene inserts are oriented in the pSP vectors for synthesis of RNA transcripts complementary to cellular oncogene mRNAs. Reaction maps and recommended laboratory procedures are provided with each probe.

Also available are OSI™ monoclonal antibodies, provided as HPLC purified immunoglobulins. Vials contain 0.2 µg of immunoglobulin in 1.0 ml of buffer. The use of denaturing HPLC procedures assures optimal product purity and consistency. These reagents are supplied with recommended procedures for laboratory methods such as immunoprecipitation and histopathology staining.

For additional information on current and future OSI™ DNA probe and monoclonal antibody products, please contact:

nature

NATURE VOL. 316 25 JULY 1985

COVER

The satellite laser ranger at the Royal Greenwich Observatory, Sussex. The Nd:YAG laser system generates 30-mJ pulses at 532 nm of 150 picosecond duration. Detection of a single reflected photon can provide a ranging accuracy of 5 cm over 6,000 km. This issue celebrates the 25th anniversary of the announcement of the world's first working laser by T.H. Maiman (*Nature* 187, 493; 1960). The history of laser development and current research programmes are reviewed on p.291, p.300 and pp.307-330. The world laser market is discussed on p.373. Advice from Dr Peter Knight is gratefully acknowledged.

Hot on delivery...

...cold on arrival

When you order molecular biologicals from Pharmacia you'll find we're pretty hot on delivery.

We'll dispatch your order as soon as we get it, packing it carefully in wet or dry ice.

Now our enzymes are supplied in screw cap mini vials with new waterproof labels, and will easily fit into your centrifuge

tubes and freezer trays.

At Pharmacia Molecular Biology Division that's all part of the service. We realize that the success of an experiment depends on the quality of the products used and the speed at which you get them. With us you'll find that the only thing kept on ice is your product - not your

experiment.

Contact us today and we'll send you our free catalogue with details of over 800 molecular biologicals.

Pharmacia... your partner in molecular biology.

SCIENCE IN AUSTRALASIA

Australia and New Zealand are most alike in their great distance from everywhere else. Both maintain scientific establishments comparable with those of Europe and North America. In *Nature's* special Australasian issue, Alan Anderson and John Maddox describe their special problems and particular achievements in research and development, and recommend what should be done.

Copies of this special issue are available now.

Australian orders should be sent to:

John Rosenbloom, Macmillan Co. of Australia Pty Ltd., Locked Bag 12, South Melbourne 3205, Victoria, AUSTRALIA. Telephone: (3) 6998922.

Please enclose remittance of A\$6 per copy.

Prices and order address for other countries are set out below.

NATURE CLASSIFIED

Professional appointments —

Research posts — Studentships —

Fellowships — Conferences —

Courses — Seminars — Symposia: Back Pages

Next week in *Nature*:

- Can spores survive in space?
- Neutrinos from Cygnus X-3
- Nuclear power stations as antineutrino background
- Dust in Sahel drought
- North Pacific aluminium
- Naming deficit after cerebral infarction
- Neuronal and cardiac calcium channels
- *Mycobacterium leprae* antigens cloned
- Arthritis and immunoglobulin
- Innovation and academic research

GUIDE TO AUTHORS

Authors should be aware of the diversity of *Nature's* readership and should strive to be as widely understood as possible

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an italic heading of about 50 words.

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are

Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or Washington. Manuscripts should be typed (double spacing) on one side of the paper only. Four copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc, should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc, should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts, in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963-65). The first and last page numbers of each reference should be cited. Reference to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Requests for permission to reproduce material from *Nature* should be accompanied by a self-addressed (and, in the case of the United Kingdom and United States, stamped) envelope.

UPDATE IN MOLECULAR BIOLOGY 1985

Genes and Systems in Development

You are invited to join a select group of participants and some of the world's foremost speakers at NATURE's fifth international conference.

Presented in conjunction with the University of California at San Francisco.

**OCTOBER 7, 8, 9, 1985—SHERATON-PALACE HOTEL
SAN FRANCISCO, CALIFORNIA**

The 1985 conference presented by NATURE, the international weekly journal of science, in association with the University of California at San Francisco will address what is perhaps the central unanswered question of biology today: How is the process of development directed by genes?

For three days, you will meet and listen to preeminent scientists, physicians and biotechnologists describe their research and first-hand involvement in experimental approaches involving the application of molecular biology to systems and organisms. Topics will include the diagnosis and therapy of genetic defects, homeotic genes, yeast development, development of the immune system—including T-cell receptors—and the use of new biological materials in medicine and industry. Roundtable discussions will be held each afternoon to give delegates ample opportunity to mix with and question the speakers. Participants will have an opportunity to take part in detailed discussions and present their own ideas. Poster presentations are also being invited.

WHO SHOULD ATTEND

Senior Level Scientists, Medical Research Scientists, Biotechnologists, Scientific Policy Makers, R & D Scientists, Departmental Chairpeople.

TO REGISTER FOR THE CONFERENCE

Return the form with your check, credit card authorization, or an authorized purchase order.

Full 3-day registration fee: \$375.00

Pay only \$350.00 if you register before September 15.

LOCATION

The Sheraton-Palace Hotel located at 639 Market Street

is convenient to the business and financial districts as well as downtown's most stylish shops and finest restaurants. Since its opening in 1875, this elegant hotel has hosted such world figures as seven U.S. presidents, Winston Churchill, Nikita Krushchev, Sarah Bernhardt, Enrico Caruso and Oscar Wilde.

ROOM RESERVATIONS

A large block of rooms has been set aside for attendees at preferred rates. However, we suggest you make your reservations early as delegate places and accommodations are filling fast. Rooms can be reserved directly with the Sheraton-Palace Hotel by calling 800-325-3535. Be sure to mention your participation in the NATURE 1985 Conference to qualify for special rates. Singles: \$95. Doubles: \$105 and \$115.

CMEs WILL BE AWARDED

Extended Programs in Medical Education of the University of California School of Medicine in San Francisco designates this continuing medical education activity for 18 credit hours in Category 1 of the Physician's Recognition Award of the American Medical Association and the Certification Program of the California Medical Association.

BURSARY PROGRAM

Bursary program for selected graduate students to be announced during August 1985.

POSTER SESSIONS

To have your poster considered, please include a working title and brief synopsis of your topic and send to Posters Editor, Nature Publishing Company, 65 Bleecker Street, New York, New York 10012

FINAL PROGRAMME

Genes and Systems in Development: *Nature* Update in Molecular Biology, Sheraton Palace Hotel, San Francisco, 7-9 October 1985.

DAY 1 MONDAY, 7 OCTOBER

8 45-8 50	Chairman	
8 50-9 40	<i>Drosophila</i> early development	C. Nüsslein-Volhard, Max Planck, Tübingen
9 40-10 30	Genetic control of <i>Drosophila</i> development	D. Hogness, Stanford University
10 30-11 10	COFFEE	
11 10-12 00	Comparative expression of homeobox genes in fly and mouse	W. McGinnis, Yale University
12 00-1 30	LUNCH	
1 30	Chairman	
1 30-2 15	Cytoplasmic localizations in the amphibian egg	J. Gerhart, University of California, Berkeley
2 15-3 00	Genes that control nematode cell lineage	H.R. Horvitz, Massachusetts Institute of Technology
3 00-4 00	ROUND TABLE with day's speakers	
4 00-4 30	TEA	
4 30-5 30	Closing talk	G. Stent, University of California, Berkeley

DAY 2 TUESDAY, 8 OCTOBER

8 45-8 50	Chairman	
8 50-9 40	A master regulatory locus that determines cell specialization in yeast	I. Herskowitz, University of California, San Francisco
9 40-10 30	Regulatory proteins in bacteria and yeast	M. Ptashne, Harvard University
10 30-11 10	COFFEE	

11 10-12 00	Simple and combinatorial regulation of gene transcription	K. Yamamoto, University of California, San Francisco
12 00-1 30	LUNCH	
1 30	Chairman	
1 30-2 15	Control of animal growth by gene transfer	R. Palmiter, University of Washington, Seattle
2 15-3 00	Models for human gene therapy	T. Friedmann, University of California, San Diego
3 00-4 00	ROUND TABLE with day's speakers	
4 00-4 30	TEA	
4 30-5 30	Closing talk	E. Jaworski, Monsanto Company

DAY 3 WEDNESDAY, 9 OCTOBER

8 45-8 50	Chairman	
8 50-9 40	Structure analysis of T-cell recognition	M. Davis, Stanford University
9 40-10 30	Expression of immunoglobulin genes in transgenic mice	U. Storb, University of Washington, Seattle
10 30-11 10	COFFEE	
11 10-12 00	Proto-oncogenes: the good and the bad	J.M. Bishop, University of California, San Francisco
12 00-1 30	LUNCH	
1 30	Chairman	
1 30-2 15	Cell recognition during neuronal development	C. Goodman, Stanford University
2 15-3 00	Molecular insights into mammalian systems	F. Bloom, Research Institute of Scripps Clinic
3 00-4 00	ROUND TABLE with day's speakers	
4 00-4 30	TEA	
4 30-5 30	Closing talk	D.W. Martin, Genentech

**SAVE \$25
IF YOU
REGISTER
BEFORE
SEPT. 15!**

REGISTRATION FORM

To register for NATURE UPDATE IN MOLECULAR BIOLOGY 1985, mail this form with your payment to: NATURE PUBLISHING COMPANY, 65 Bleecker Street, New York, NY 10012

(Photocopy this form for additional applications.)

Please reserve _____ Conference registration(s) in the name of: (please type or print)

_____ and _____ seats

at the Tuesday Conference dinner in the name of: _____

NAME _____ TITLE _____

COMPANY/INSTITUTION _____

ADDRESS _____

CITY _____ STATE _____ ZIP _____

I understand that as a paid conference participant, I may attend all sessions and receive all programs and other materials.

My check for \$ _____ is enclosed.

Charge my credit card as shown.

☐ Amex ☐ Visa ☐ Mastercard

Credit card number _____ Expiration date _____

Signature (as it appears on card) _____ ☐ Bill me. ☐ Bill my organization.

REDUCE BACKGROUND

With Sequencing Grade Triphosphates From Pharmacia

Ultrapure Deoxynucleoside Triphosphate Solutions

While often overlooked, high quality triphosphates can increase gel clarity considerably, allowing reading of up to 30% further from a single primer site. Pharmacia's solution triphosphates are the most stable, homogeneous and diphosphate free nucleotides available. In addition, they can be used without weighing, neutralization or concentration determination.

2',3'-Dideoxynucleoside 5'-Triphosphates

Ever since we provided the first commercial dideoxynucleosides in 1977, researchers have relied on our ultra-pure 2',3'-dideoxynucleoside 5'-triphosphates for the specific chain termination and low background needed in their sequencing.

Keep your results clear of the background.

Where next after Geneva break?

The Geneva arms control talks have adjourned without breaking down, which is something to be grateful for. The negotiators should spend their break deciding where to go from here.

THE prospect that something will come out of the bilateral arms control negotiations at Geneva, far from being dimmed by last week's adjournment, is enhanced because they have not long since broken down. That the negotiations would be difficult has been clear from the start even though those that broke down at the end of 1983 covered some of the same ground. This time, the problems at Geneva have been complicated by its announcement of the US plan to build a defence against strategic missiles, an issue that seems not unduly to have alarmed the Soviet Union during the earlier abortive talks. The best hope now is that the two sides will use the summer to work out the skeleton of an agreement that might be put to Mr Reagan and Mr Gorbachev when they meet, as they intend next November. But even that is a lot to hope for.

The present position is both complicated and delicate. The United States, which spent the years preceding the Anti-Ballistic Missile (ABM) Treaty of 1972 in trying (successfully, in the end) to convince the Soviet Union that ballistic missile defences would be dangerous, is now faced with the task of demonstrating that the opposite is the truth, that a workable shield against hostile missiles would be a boon. Inevitably, the logic must sound thin. Yet the United States is within its rights to insist that research programmes cannot be the subject of international treaties (because verification is impossible), while the Soviet Union can rightly say that some of the testing planned by the Strategic Defense Initiative (SDI) would violate the ABM treaty, as would the emplacement in an Earth orbit of a radar system for detecting hostile missiles, whether or not it was accompanied by a device for shooting down unwanted objects.

Understanding

The signs are that the Soviet Union is now willing to accept that research cannot be prevented by bilateral agreements. What the United States should in return be willing to accept is that successful research cannot be followed by development without violating the 1972 treaty so the need is for some general understanding (not at this stage a treaty) on mechanisms for modifying the ABM treaty by agreement. That, in any case, is about the only way in which the United States could hope to win support in Western Europe for its plans, and also the best way to avoid the increasingly bruising squabbles in Congress about money for SDI.

But how is it possible to agree in advance on procedures for modifying a treaty without knowing what changes will be required? The difficulties are fewer than they appear. The ABM treaty itself is, by its symmetry, a useful guide. In the original version, each side was allowed to protect only two regional targets, one city and one missile field. Each was allowed to build phased array radars, but only on its periphery, and directed outwards. There were restrictions (whose observance is not

easily verified) on the uses that might be made of anti-aircraft missiles. The general principle was that each side was allowed to follow, if it chose, prescribed courses of action. (In the event, the United States decided not to take up the right to deploy anti-missile missiles, the Soviet Union exercised only one of its two options.) So it might sensibly be agreed that any later modifications of the ABM treaty would follow the same principles. The first practical component to emerge from SDI is almost certain to be a recipe for an orbiting early-warning system which, if not accompanied by defences, could do no harm. So why not agree now to agree later on how such a system should be specified, and agree that each side should be entitled to one of them? And so on with the other planned components of SDI, as and if they become practical realities?

The rest of the Geneva agenda similarly cries out for re-examination. The serious flaw in the abortive negotiations of 1983 was that strategic and intermediate-range missiles were rigidly kept separate. The separation is now less complete, which is just as well when it is reckoned that missiles such as the Soviet SS20 and heavy bombers based in Europe have a similar strategic function in a European context. One obvious difficulty now is that so much time has passed since the Salt II agreement (1978) that each side probably needs, for good military reasons, a more modern strategic missile. The US need of something more credible than the MX missile stands out a mile. So here again is an opportunity for reciprocal modification of the existing agreements — permitted modernization coupled, say, with a target number for total warheads reducing steadily over some specific period ahead, something like a decade. There would be opportunities in such an arrangement to use the "build-down" principle in fashion two years ago — one new missile for each two old missiles destroyed. An arrangement like this would let ordinary people sleep more easily in their beds, but also keep the generals happy. But why bother about them? Because an agreement that lets one side feel permanently at a disadvantage will not stick. □

Reaganomics found out

The US economy is heading for stagnation and the need to cut the deficit is more urgent.

BUDGET directors, wherever they work, are not often popular, so that there are rarely floods of tears when they quit their jobs. The departure last week of Mr David Stockman, director of the US Office of Management and Budget since 1981, should be differently regarded. His continued presence at the White House has been for the past three years the best chance that something would be done to reduce the federal government's budget deficit, expected to exceed \$200 million in the year beginning on 1 October. The chance, recently only an off-chance, has no doubt been further diminished by President Ronald Reagan's abdominal operation, while the past week has seen such a confusion of signals about the condition of the US economy from the stock markets and the foreign exchanges that the most resolute members of the US Congress are likely to be given pause. However, this is not the time for masterly inaction.

Biological manuscripts

Contributors are reminded that, with the transfer of the Biological Sciences Editor to the Washington office, it will be helpful if they will in future send **four copies of all manuscripts** offered for publication, either (as at present) to London or Washington.

The past five years have been a topsy-turvy period when it seems to have been possible to make water run uphill. At the outset of the administration, the objective was to cut taxes, in the belief that an industrious industrial economy would make such good use of the extra money that wages and salaries would rise several times as much, thus restoring the federal government's revenues. Taxes were indeed cut, and there has been a remarkable increase in the number of potential taxpayers at work in the United States. But tax incomes have not increased to bridge the revenue gap. So the second and unplanned phase of Reaganomics, most of the past three years, has been a period during which the federal government has bridged the gap of borrowing in the markets, ultimately from overseas.

Inflation has been restrained by the determination to borrow (rather than to print money), economic growth has picked up in spite of historically high interest rates (necessary to tempt in funds from overseas) and the US dollar has been over-valued. The trade deficit, likely to exceed \$140,000 million during this calendar year, is the other side of the same coin, but that is the reason why the pace of economic growth has now declined almost to nothing, at least for the first half of this year. And now, not surprisingly, the value of the dollar has begun to fall. The third phase of Reaganomics has begun. We can only wait and see what it will be like.

The immediate temptation in Washington will be to go slow on attempts to cut the budget deficit. Members of the Congress who have been sharpening their knives will now be given pause by the apparent lack of growth between the first half of 1984 and the first half of this. The Keynesians among them and many others will be saying that a time of stagnation is the wrong time to be taking money out of the system. The hitch in that argument is that if the deficit persists, it will be necessary to increase interest rates again, which may have the same effect, putting a drag on US industry and intensifying the stagnation now in prospect. This is what Mr Paul Volcker, the chairman of the Federal Reserve System, was saying in Washington last week. The alternative would be to embrace inflation, which could easily become the hallmark of phase three.

That is why the United States has no choice but to look overseas for a solution. Japan and, latterly, West Germany have been earning large surpluses in their overseas trade, chiefly from that with the United States, and have obligingly lent that back to the United States. In principle, both governments (and some others) could help avoid the present prospect by allowing their own domestic demand to increase, either by lowering interest rates or (better not) by apeing the first phase of Reaganomics. But none of this is arithmetically possible unless the US budget deficit is cut. How else could Japan and West Germany earn the surpluses with which the US Treasury expects them to bridge its gap? The simple moral is that there should be a negotiation between the three countries principally concerned to decide which deficits should be cut by how much. The pity is that the chance to do this, last month's meeting in Bonn, has been let slip. And next year's meeting in Tokyo is too far away. □

University on brink

The changed University of London could be fun to watch.

The University of London is, or at least was, a remarkable institution. It is the only really large university in Britain, with more than 20,000 undergraduates. Not so long ago, it had no fewer than a dozen distinct medical schools, and a similar number of medically oriented postgraduate institutions. There is also a handful of specialized centres within the university concerned with matters as different as oriental languages and fine art. Until a quarter of a century ago, the University of London played a kind of authenticating role in British university life, acting as the validating umbrella beneath which sheltered a number of institutions that are now universities in their own right. During the same period, the university also ran single-handed a system of

public examinations for secondary schools throughout what was then the British Commonwealth, a function that has been eroded as much by the wish of Commonwealth countries to run their own affairs as by the university's choice.

The past few years have seen even more rapid change, largely because of the shortage of funds. Five years ago, a committee under Sir Brian (now Lord) Flowers advocated that the number of medical schools should be reduced, by mergers, to a half, and there have indeed been some moves in that direction. More recently, the main teaching establishments of the university have also been reduced in number. Small Bedford College has moved out into the country to merge with another small teaching school, Royal Holloway College, on a site more than twenty miles from central London. Two others (Chelsea College and Queen Elizabeth College) have merged (with effect from 1 August) with King's College to form an institution with more than 6,000 students (plus a medical school). The result is that the university's main teaching functions are for the first time concentrated in a handful of institutions, four large establishments (Imperial, King's, Queen Mary and University Colleges), Birkbeck College which has a special interest in part-time students, the London School of Economics and the amalgamation in the Surrey countryside. (One small college, Westfield, looks like sinking without trace unless it decides in the next few weeks to merge with the new King's College, to be known as KQC for the next five years.)

The objective of these upheavals was originally to save money, and that may eventually be possible. More immediately, however, the crying need is to find capital with which to make the planned amalgamations into effective teaching institutions. With the real funds at the disposal of the University Grants Committee shrinking by between one and two per cent a year, and with little prospect that the British government will dig into its pocket to help out just one university, much of the brave planning of the past few years may come to nothing. The most obvious danger for the colleges (and those who teach in them) is that the grants committee will be forced by sheer penury to shrink student numbers until the existing buildings will accommodate them.

The university is not well placed to defend itself. Administratively it is a mess. Although students at each of the teaching establishments are in theory members of the university as a whole, in practice the large institutions are separate and autonomous. Students are taught where they are recruited, and the different colleges distinguish carefully between each other's degrees. Financially, the colleges are supported by funds from the central federal university (but Imperial College deals separately with the grants committee on the grounds that it is a technological centre of national importance). Everybody agrees that the procedures for sharing out the funds are unsatisfactory, primarily because the customers are never helped to understand the principles on which decisions have been made. The system is also cumbersome; it is a standing joke that the University of London is usually about a year late in replying to the questionnaires that have been a standard part of university administration.

Left to itself, the university would probably collapse under its own weight in the years ahead. Now that the federal university's main teaching functions are no longer distributed among small as well as large institutions, the temptation to circumvent the university machinery, and to deal directly with the grants committee, will be strong. The result would be that the richness of the present diversity within the university would be lost. Most academics within the university know that to be the case, but there is also a limit to their willingness to put up with an administrative system which is not merely cumbersome but which lacks intellectual coherence. The challenge for the university's bosses and in particular for Lord Flowers, the head of Imperial College who takes over as vice-chancellor of the university next month, is that of deciding whether there is a way of keeping the university together and then of persuading those who work in it to follow such a course. It will be a struggle, but one worth making. □

Defence research

Defence to support UK academic research

IN a move that could more than double its financial support for university research over the next three years, the British Ministry of Defence (MOD) is embarking on two new collaborative schemes involving universities, industry and its own research establishments. The increase in funds, amounting to anything up to £15 million on top of the £9 million already spent annually on direct collaboration with universities, will come from MOD's research budget, now running at about £380 million per year.

More than one third of MOD's research budget is spent externally, most of it in industry on applied research with specific

applications in mind — not to be confused with the funds spent on development, which in total amount annually to £1,900 million. But a small percentage of the research money goes into strategic ("seed-corn") research. About five per cent of work carried out in the research establishments falls into this category. Externally, MOD supports some 650 research projects among 72 universities, colleges and polytechnics.

For some time, academics suffering a steady squeeze in funds for science have been casting covetous looks at MOD's resources, comparing, for example, its £380 million research budget with the £280 million available to the Science and Engineering Research Council (SERC). Partly in response to concern that it should generally seek to do more for the country's science base, but partly because of its own need to increase the return on its funds, MOD has set up a collaborative scheme for university research grants with several of the research councils, particularly SERC and the Natural Environmental Research Council (NERC).

The new scheme, to start towards the end of this year, should involve only minor change in the councils' grant funding procedures. Applicants will be invited to indicate whether they are interested in, or opposed to, part support by MOD. Following peer review, research staff in MOD will assess appropriate grant proposals and offer up to 50 per cent of the required support. The councils will then decide whether to provide the balance.

Both MOD and the research councils emphasize that the new scheme should not bend council funds towards defence-related research. And an MOD spokesman says that grants with significant defence relevance that fail to obtain council support may still be taken up by MOD. Furthermore, jointly funded research projects will be subject to restrictions on publication only when patents are involved or when researchers move into classified areas. Such occasions "are conceivable", according to the spokesman, "but we will bend over backwards to keep work unclassified. Our aim is not to be bureaucratic." Recent restrictions on US researchers by their Department of Defense, such as the much publicized cancellation of sessions at a recent physics conference, are viewed at MOD with disfavour.

MOD is to circulate every university with a portfolio explaining the scheme and listing the specific areas of primary interest together with names of principal MOD researchers so that interested academics can establish informal contacts. The research councils will issue announce-

ments of opportunity for grant applications, with a deadline of 1 December.

A second scheme for university collaboration is being set up by MOD that will involve the research councils only peripherally through their peer review panels. This scheme has been stimulated by MOD's experience of the Alvey scheme for university/industry collaboration in information technology, and will aim to stimulate such activity in other areas of defence-related research. MOD would support the whole of the university component, to the tune of £1 million in the first year increasing to about £4 million in 1988. By that time, MOD expects to spend £5 million annually on the collaborative grants scheme and £6 million direct to the universities. But if the demand is strong enough, a further £5 million could be available.

Phillip Campbell

University of Geneva

Illmensee's view

WITH the collaboration of others in his laboratory, Dr Karl Illmensee is still hoping to reproduce some of his early experiments on mice before he leaves the University of Geneva in September 1987. The difficulties in doing so, he said this week, are partly the result of continual interruptions caused by the need to attend to administrative affairs connected with the events that led him not to seek an extension of his contract with the University of Geneva (see *Nature* 11 July, p.98).

"The climate here is so hostile that there is no possibility to do research", says Illmensee, and "there is false information" in the internal report that was to have been submitted to the faculty meeting that would have considered extending his contract beyond September 1987.

Apart from interruptions from the university and the press, says Illmensee, the problems of repeating some of the past results are normal scientific difficulties. He has sufficient financial support from the university to attempt to reproduce past experiments and to continue with some of the research that has been interrupted, in close collaboration with others in his laboratory. These include three postdoctoral scientists, one from Hungary and two from West Germany, who have joined the laboratory in the past year.

"My priority", says Illmensee, "is to repeat the experiments of 1982 involving teratocarcinomas." The problem, he claims, is still that of re-establishing the teratocarcinomas. The second priority is to repeat the 1977 production of homozygous diploid mice using a technique that nobody has been able to reproduce. "I have no idea if the time (until September 1987) will be sufficient for me to complete these experiments", he says.

Peter Newmark

Genetic engineering patents

Interferon interference

LEGAL tussles over the commercialization of alpha-interferon have taken a new turn with the filing in Vienna by Biogen NV of a complaint against Boehringer Ingelheim Zentrale GmbH for its marketing of a product containing an alpha-interferon produced by recombinant DNA technology. Last August, Biogen was granted a broad European patent for "recombinant" alpha-interferons. Boehringer Ingelheim is one of several companies that have registered their opposition to the patent with the European Patent Office.

Biogen, of Geneva, Switzerland, and Cambridge, Massachusetts, is suing the West German pharmaceutical company Boehringer Ingelheim over an eyedrop for the treatment of keratitis caused by the herpes simplex virus that has been marketed in Austria since early this year. Acknowledging that the product contains a recombinant alpha-interferon, Dr Dieter Laudien, head of the Boehringer Ingelheim patent department, says that the company, and its subsidiary Bender, does not believe that Biogen's patent can be enforced.

Its opposition, lodged with the European Patent Office in May, is based mainly on evidence that enough information about alpha-interferon and its sequence was known and published before Biogen's patent filing to make Biogen's achievements "non-inventive". By starting its lawsuit against Boehringer Ingelheim, Biogen has clearly signalled that it is optimistic that its European patent will survive the opposition when the matter is considered, probably in a few months time. Meanwhile Biogen is still expecting to receive patent protection in the United States despite the rival patent granted to Hoffman-LaRoche (see *Nature* 21 March, p. 207).

Peter Newmark

Space business

Suppliers ready to break rules

Washington

THE Office of Technology Assessment (OTA) of the US Congress has paid the international space industry the compliment of an economic analysis of its prospects not very different from what might be written about an established industry. In a report published this week, *International Cooperation and Competition in Civilian Space Activities*, OTA says that attempts at international collaboration will probably be blocked by national policies, but recommends that, wherever possible, governments should let space industries develop along unregulated lines.

Much of the report is meant to alert US industry to the emergence of competition in some space activities in other industrialized countries to which, the report says, US policies have not fully adapted. The report identifies the members of the European Space Agency (France in particular) and also Japan as the chief sources of competition during the coming decade.

Space activities are still predominantly within the domain of government, according to OTA. And the big spenders are the United States (which spent \$17,500 million in 1984 on civil and military applications) and the Soviet Union (which is said to have 600,000 people working in the field). US spending is 20 times that of the European Space Agency (ESA), and is the equivalent of 0.47 per cent of gross national product (GNP) compared with 0.08 per cent for France, the next in line.

OTA thinks it unlikely that there will emerge a competitive environment for trade in space-related services and products. "Since France and Japan... have made the decision to join the United States as space powers, it would be wishful thinking to believe that they will fully abide by the trade rules.."

Even within the United States, OTA is not convinced that there will be enough business to tempt private companies into the provision of launching vehicles, as three aerospace companies (Transpace carriers, General Dynamics and Martin Marietta) are in principle equipped to do. The report also says that the foreseeable demand for launching facilities is what it is at present — the need to put communications satellites in orbit — and that other satellite uses, such as for remote sensing and materials processing, "are even more uncertain".

The volume of demand should nevertheless be enough to keep both the US shuttle and Ariane fully occupied. According to figures compiled by Rockwell International and quoted by OTA, the combination of civil and military needs in the United States would be enough to occupy 24 shuttle flights a year by 1988, with possible demand making necessary a further 20 flights a year in the succeeding

five years. These calculations assume that Ariane would be making 10 flights a year from now on.

If these estimates are correct, OTA says, there may be a need for extra launching capacity by 1988. But if the US defence needs are in part met by some other launching mechanism, either the shuttle or Ariane could be under-occupied between then and 1994. Those are the circumstances in which competition might occur.

At what price? The cost of a dedicated shuttle flight has already increased from the \$18 million estimated in 1975 to something like \$80 million now, but OTA points out that this is considerably less than the real cost of the five shuttle flights in 1983, which are estimated to have cost \$375 million each. By 1988, when overhead costs will be spread over more launches, it may still be necessary to charge more than \$100 million for a dedicated launch.

At these rates, OTA says, the shuttle should still be cheaper than Ariane as a launching vehicle for geosynchronous satellites (which is reckoned to amount to \$20,000 for each pound of mass in orbit). But competition may be hindered by the terms on which launching services are offered; the US National Aeronautics and

Space Administration (NASA) is required to ask for all the cost in advance, but Ariane's managers take graduated payments.

OTA offers the US government a series of policy choices on the shuttle. If, the report says, the objective is to capture a large percentage of the commercial demand for satellite launchings, the result will probably be increased demand for use of the shuttle, perhaps even a need for more orbiting vehicles, and increased cost. If the US government were deliberately to encourage private US companies to enter the business, they would probably compete successfully with Ariane, but NASA's role as a space carrier would be reduced. The report also points out that a strategy intended to make the shuttle the vehicle to meet "all current and future" needs in the United States would greatly increase the cost of the shuttle programme and probably put Ariane out of business.

On the business of building communications satellites, OTA argues that US suppliers are the cheapest source of hardware (in spite of the strong dollar) and were able to compete successfully for the contracts to build all 20 of the Intelsat consortium satellites to be launched in the period 1984-89. But OTA notes that all 19 European satellites to be launched for European owners during the same period will be built in Europe, as will be the nine planned Japanese satellites to be built in Japan. □

US pharmaceuticals

Monsanto and Searle to merge

Washington

THE planned merger of Monsanto and G.D. Searle, announced last week, will provide a quick shot in the arm for Monsanto's growing interest in drugs for human disease. The move will also give Monsanto access to a distribution network for pharmaceutical products, the development of which is one of the objectives of the recently expanded research facility at the company headquarters at St Louis, Missouri.

Although the Searle family, which at present owns 20 per cent of the stock in G.D. Searle, has made no secret of its wish to diversify its interest since last September, the planned merger appears to have taken the pharmaceutical industry by surprise. The plan is that Monsanto should offer to buy all the outstanding shares in G.D. Searle for a total cost of \$2,700 million.

The combined operation will have total sales of \$8,000 million a year, with Searle rather less than 20 per cent the size of Monsanto. Both businesses have substantial interests very different from their point of overlap in biotechnology, which appears to have been one of the chief reasons for the merger. Monsanto is primarily a manufacturer of plastics and agri-

cultural and general chemicals, while Searle in the past two years has become, at least temporarily, the predominant supplier of the artificial sweeteners based on the di-amino acid aspartame.

Both companies have taken a close interest in biotechnology in the past few years. Searle, which has three major laboratories worldwide, has built up the laboratory at High Wycombe in Britain (with a complement of 600) to be a major centre of research in recombinant-DNA techniques. Monsanto's directly comparable interest is the somewhat smaller unit based at its Life Sciences Center at St Louis, opened formally only last year.

A spokesman for Searle said this week that the two research enterprises were likely only to reinforce each other. With the St Louis laboratory at the beginning of what is likely to be a period of growth and consolidation, the High Wycombe laboratory could well have the advantage of possession of the ground in any reorganization that comes about. But, formally, nothing can be done until Monsanto has made its formal offer for the shares of G.D. Searle, won the acceptance of a majority of the holders and then decided where it will raise the funds with which to pay for them.

John Maddox

Academic innovation

Cambridge science park succeeds

LIKE a well-focused laser beam, the Cambridge Science Park (CSP) is hot in the middle. Its heat is that of fast growth — witness the new construction in every direction, the rising profit margins of the companies and the traffic jams outside the park.

This growth of high technology in a previously "backwater" university town has inspired a flurry of analysis about the reproducibility of the CSP experience and its long-term growth. How fertile is the industry/university link for jobs and increased income? Cambridge has been compared to the early Silicon Valley; does it also need the anchor of big companies with a marketing mentality gauged to the mass market rather than to the specialized niche?

CSP, with its 40-odd companies and 1,000 employees, is only a small part of what is now popularly called the Cambridge phenomenon. Since the early 1960s, some high-technology companies employing 14,000 people have been established in Cambridge, most of them with direct links to the university. CSP's acknowledged role is as symbol, proof and drawing card for what is happening in Cambridge. It is not, however, simply a further extension of that activity. Located just outside the town on land owned by Trinity College, CSP has high-rent buildings, lots of open space, a lake complete with rather antagonistic geese and its own personality.

The scarcity of good industrial sites in Cambridge means that CSP is one of the best places in the area. For this reason it attracts not only Cambridge companies that are growing or moving upmarket but also companies from outside the region which come because of Cambridge's reputation and because Britain's oldest science park is now a good address. They come to get away from "metal-bashing" industrial centres to a town where the air is clean. And increasingly they come to CSP because of its accumulated experience in getting new technology into established industry.

Many CSP companies such as Laser-Scan Laboratories, with its laser-deflection display devices for location of aircraft in distress, use computer technology; the hardware/software companies themselves, however, have so far chosen to stay in town, close to the university computer facilities. Spin-off companies are common among these, as they are in Silicon Valley and on Boston's Route 128. Because of CSP's small size and high specialization, there is less interaction among companies at the park.

An important factor in CSP's growing success is the unconventionality of the "oddball" entrepreneurs. Ideas that might previously never have seen the light of day

outside an academic journal are now not only taking reproducible form but are also making money. At one turn, for example, Dr Felix "Polywater" Franks has turned his expertise to water in supercooling cells. At present, genetic engineers and companies doing drug tests on cell lines freeze their cells to preserve them. "Cells are contrary beasts", says Dr Franks; even if they can be frozen, they are often killed or experience genetic drift. Supercooling, according to Franks, keeps the cells alive and pure.

Another innovator is Andrew Goodfellow of Goodfellow Metals, which specializes in thin films and in changing the surface properties of metals by ion implantation. Goodfellow commercialized one of the first Cambridge inventions to become a success — the Huxley-Goodfellow micromanipulator originally designed by Sir Andrew Huxley. Britain, according to Mr Goodfellow, "breeds a nation of losers". The most important difference at Cambridge is the attitude of mind fostered there.

Dr William Bolton, of Cambridge Robotics, runs a tiny company involved in dedicated electronics for foundries. He sees his role as educating both engineering graduates and foundry management, showing the former that the problems of the assembly line can be challenging and providing the latter with graduates already experienced in technical and financial issues.

The Microelectronics Research Laboratory is so far an anomaly at CSP because it is a university facility. Many of the projects the laboratory works on, according to the director Dr H. Ahmed, are of direct benefit to industry. Examples include research on electron and ion beams, as well as new ways of putting silicon on top of insulators. The laboratory does not do contract research but, instead, collaborates with interested companies, a sharing that often results in joint publications.

Trinity's role as owner of the CSP land places it in a special relationship to the occupants of the park. The juxtaposition of high-technology companies with a college known for scientific excellence might be expected. On the other hand, this marriage of interests is an oxymoron: the universities in Britain have traditionally had nothing to do with applied research, and the timescale of Cambridge, "where things are happening fast if they are promised by next term", is antipathetic to the aggressive speed of high technology.

This timescale has its advantages. Dr J. Bradfield, senior bursar of Trinity College, says that growth was slow before 1980, but because Trinity owned the land already, looked at projects in terms of decades if not centuries, and had no speci-

fic plans for CSP, the park was never in danger of being labelled a failure. In addition, though Trinity definitely wants a close relationship between the CSP industries and the university, it sees no reason to force or formalize them. Here is the crux of the industry/university bridge; according to Bradfield, it is the "accidental and unexpected friends" that provide the finest spark.

Trinity's support of CSP has been an important catalyst for the entire Cambridge phenomenon, lending confidence to the movement according to Dr Nick Segal, whose firm Segal Quince & Partners recently published a report on Cambridge high technology. Dr Bradfield points to the 1960s debate over the role of the university and Cambridge's image as unindustrial (as opposed to Oxford) and quaint. Now, according to Dr Bradfield, CSP has shown that applied research can achieve "results of great interest that also make money".

Acceptance for the changing dynamic of university research and industry is expressed in many different ways. According to Dr Peter Woodsford of Laser-Scan, a scant five years ago his company was not allowed to specify the kind of work a Cavendish research fellow that it funded would pursue. He believes he would have such freedom now.

CSP's growth curve, says Dr Bradfield, is virtually classic in form; a slow first few years followed by a steep rise. CSP insiders agree that CSP, along with the entire Cambridge phenomenon, is still far from reaching a plateau.

As for second-stage growth of the Cambridge phenomenon, one issue is how many small companies will be bought out — a trend already begun between US companies and CAD firms in town. Dr S. Bragg is head of the Wolfson Industrial Unit, whose business is providing bridges between industry and university. He predicts that small enterprises will continue to be started, but cannot say whether existing companies will grow suddenly or stay the same size.

CSP's success will be a function of the model analysts apply. There is no reason why a large number of small companies should not provide at least a certain volume of employment and income, at the same time retaining flexibility by constantly bubbling new ideas to the surface. Failing companies would be quickly replaced. It is tempting, however, to apply another model — the leaven of large firms governed by a marketing mentality that thinks in billions, not millions — because this model applies to the older larger science parks in the United States. Large companies offer widespread use of products, lots of jobs and the promise of stability. Already there is an IBM "listening post" on CSP. But for many of the innovators there, big fish moving into their pond would not be a welcome transformation.

Elizabeth Collins

UK laboratory animals

Experimentation reduced

THERE are signs that the pressure of public opinion has caused researchers to think more carefully about experiments on living animals. The number of such experiments in Britain decreased by 4 per cent last year. And although the number of licensed experiments has remained constant, the 3.5 million new experiments reported in 1984 is the smallest since 1959, according to statistics published by the Home Office in its annual report last week (Cmd 9570, HMSO, £4.70). Just over half of the licences to perform experiments on living animals are held by people in universities and about a quarter by those working for commercial companies; but 53 per cent of the experiments are performed now in the commercial sector and only 22 per cent in universities.

The largest decrease between 1983 and 1984, occurred in experiments on amphibians and reptiles (a 44 per cent fall) and

mice (8 per cent down). Experiments on birds and fish increased but, even here, the total is still less than that in 1980. Even cosmetics testing has been reduced, although only by 3 per cent of the amount in 1983. Of the experiments performed on live animals in Britain, almost all (80 per cent) are either to investigate safety and hazards or to look at body structure and function.

The emphasis on pain placed in the recent white paper (policy document) (Cmd 9521) on *Scientific procedures on living animals* (see *Nature* 23 May, p. 267)

is continued in the Home Office annual report. The Cruelty to Animals Act requires that animals must be anaesthetized during an entire experiment and, if the animal is likely to be affected post-operatively, killed before recovery. If this frustrates the object of the experiment, the researcher must obtain a special licence from the Home Secretary signed by the president of a learned society and a professor of medical science, as well as reporting each year on details of the experiments performed. The act only allows experiments at all for the purposes of increasing physiological knowledge or for prolonging life and alleviating suffering.

The white paper, which seeks to restrict animal experiments further, is unlikely to be debated in parliament in the next 12 months. This delay has disappointed organizations such as the British Veterinary Association, the Committee for the Reform of Animal Experimentation and the Fund for the Replacement of Animals in Medical Experiments. They feel that the white paper proposals are a necessary first step in the protection of laboratory animals and ensuring that their suffering is minimized. But the government is reluctant to set a timetable for debating such a controversial issue.

Maxine Clarke

• The 21 member states of the Council of Europe have adopted a convention that will lead to better protection of vertebrate animals used for scientific purposes. Bri-

tain will sign the convention "in the early autumn", Home Secretary Mr Leon Brittan says. Britain has played a leading role in drafting the convention and the government intends to use an article "enabling member states to adopt more restrictive measures than those laid down". The convention aims "to balance the needs of research with the consideration owing to live animals; to protect them from pain and suffering; and to ensure that non-sentient alternatives are used wherever practicable". Member states will be required to publish annually statistics on the use of animals. □

Framatome

French company still adrift

FRAMATOME, the French constructor of pressure vessels for the French nuclear reactor network, is still looking for a buyer a year after the collapse of its parent company, the steelmakers Creusot-Loire.

The reason for the delay is simply that Framatome at present does not appear a good buy. Despite the French nuclear success story, most of the reactors that France needs are already built or under construction. The government has now reduced orders to one 1,300-MW reactor every couple of years, and there is unlikely to be an upturn in orders before the oldest reactors, built in the mid-1970s, need replacement in the late 1990s. Exports of French pressurized water reactors (PWRs) have also proved almost impossible. And while Framatome will supply the pressure vessel for the first British PWR at Sizewell, if planning consent follows the public inquiry report due at the end of this year, the French fear that the British market may later be closed. British constructors are expected to get together with Westinghouse to design their own version for the world market, with the result that even if there is an expansion of PWR construction in Britain after Sizewell, Framatome may not benefit. And even if Framatome does get a place, the prospect seems far enough off that the company's immediate problems will not thereby be solved.

Thus the French atomic energy commission, which is now looking after Framatome, would like the company to diversify. Uses for nuclear pressure vessels are, however, relatively few; and Framatome staff are already beginning to fear Framatome's dismantlement. That, however, might prove to be such a political embarrassment for the present government, with nuclear power being rightly seen in France as a national success story, that it can be discounted for the time being. If, however, the right is returned to power at the next elections, it would be a simple stroke to dismantle Framatome — and blame it on the economic failures of the previous government. Robert Walgate

US animal rights

Washington

A FOUR-day sit-in by animal rights protesters at the National Institutes of Health (NIH) ended late last week with the surprise announcement by Secretary of Health and Human Services Margaret Heckler that she was meeting the demonstrators' demand for an end to NIH support of the University of Pennsylvania's Head Injury Laboratory.

The laboratory was the target last year of a break-in by the Animal Liberation Front, during which equipment was vandalized and videotapes of experiments were stolen. Researchers at the laboratory induce brain injuries in monkeys to study how damage and recovery occurs in head-injury accidents.

According to an NIH spokesman, NIH officials were already investigating complaints about violations of its animal care regulations at the laboratory when the sit-in began; the investigators' report was expedited by one day because of the protest, however.

The NIH investigators, who reviewed videotapes and inspected the laboratory, concluded that the researchers had not properly trained or supervised technicians, had performed surgery on animals in unsterile environments and had failed to use proper anaesthesia and analgesia for the animals to minimize pain. NIH left open the possibility that financial support could be reinstated. NIH director James Wyngaarden said he would make a final decision after the University of Pennsylvania has been given a chance to respond. NIH did not criticize *per se* the use of monkeys in the experiments or the experimental protocols.

Stephen Budiansky

French information

New centre for Nancy

Not before time, France is to reorganize its whole system for managing and distributing scientific information, the French government announced last week, thus responding to a long campaign by the Centre National de la Recherche Scientifique (CNRS), the principal research council, to bring the nation's libraries together in one great documentation system.

According to M. Goéry Delacote, director of scientific and technical information at CNRS, one target will be to catch up with the British Library Lending Division (BLLD), which is now central-

ized at Boston Spa in Yorkshire. Fifteen years ago, said Delacote, the CNRS documentation centre (CDST) and BLLD serviced 300,000 requests each year for photocopies of papers and other items in the sciences. Today, BLLD's computerized systems deliver 2,700,000 a year, while CDST's figure has not changed.

Something had to be done to improve the distribution of papers, a problem exacerbated by the poor financial condition of French university libraries. An opportunity came last year when the government offered to relocate the 350-staff CDST, now in Paris, in the depressed steel town of Nancy. Since many of the staff will probably choose to stay in Paris, this was an offer of jobs to Nancy, and of increased space to CDST.

There will be a new institution, the Agence Nationale de l'Information Scientifique et Technique (ANSTI), whose job will be to coordinate not only CDST but also the many university libraries, the information systems of the medical research council (INSERM), the national collection of periodical catalogues (CCNP) which centralizes the journal lists of 2,300 French libraries, and other sources into one system which should look, as far as possible, simple and unified to the potential user.

According to Delacote, the aim will be not only to increase the volume of papers transported and transmitted in France but also to increase the speed of the various services from their present "rather long" average of 10 days from request to delivery to something more like one or two. "We also want the system to be as comprehensive as possible", said Delacote, so that "95 per cent of the time" a user will find that the paper requested is available.

ANSTI is expected to recommend that the new CDST centre at Nancy will provide the basic document delivery system, will host and develop the French abstracting database Pascal (for the hard sciences) and Francis (for the humanities and social sciences), and provide a centre for information management.

And while France may appear to be coming from behind in this area, it is also moving rapidly into the overtaking lane. Delacote believes a scientific information system like CDST must invest "10, 15 even 20" per cent of its budget in research, and he has put FF25 million (£2 million) of his budget into a project for automatic document delivery dubbed "Transdoc". This experimental electronic archiving and access system is comparing optical digital disks and a microfiche archive run by a computer, and should produce a clear choice of high-volume archiving system "by the end of this year". In this France is running "parallel to or even ahead of US systems".

Robert Walgate

Jürgen Neffe

More pork-barrel politics

Washington

DESPITE condemnation by the Association of American Universities, the National Academy of Sciences and the National Science Board, direct appeals to legislators for funding of academic research facilities are continuing, and continuing to pay off. This year, once again, a number of construction grants to universities were approved on the floor of the House of Representatives and the Senate, virtually without debate; the grants had not been submitted to funding agencies previously or subjected to scientific peer review of any kind.

Topping the list this year is Dartmouth College, which, if the House agrees to the Senate's version of the 1985 supplemental appropriations bill, will receive a \$15 million grant for construction projects at its engineering school.

The grant was approved by the Senate without a vote on an amendment offered by Senator Warren Rudman, who represents the state of New Hampshire, where Dartmouth is located. That same amendment also provided \$10 million for a "south wing rehabilitation project" at the Organ Health Science University, located in the home state of Senator Bob Packwood, the chairman of the Senate Appropriations Committee.

Senator Orrin Hatch (Republican, Utah) introduced two amendments to provide support for a \$6 million cancer screening and research centre in St George, Utah, and a centre for the study of health effects of new energy technologies at the University of Utah.

Both projects had been authorized last year in amendments to the Head Start reauthorization bill which Hatch was able to push through in his position as chairman of the Labor and Human Resources Committee. Head Start is a programme that provides special tutoring to disadvantaged children.

Senator Robert Dole (Republican, Kansas), the Senate's majority leader, secured \$200,000 for a remote-sensing research project at the University of Kansas. The one contribution from the Democratic minority in the Senate was a \$500,000 amendment proposed on behalf of Senator Edward Kennedy of Massachusetts for a Chinese-US student exchange programme at Tufts University in Boston.

Earlier this year, Senator Alfonse D'Amato (Republican, New York) pushed through a measure to set aside \$1 million for a computer research programme at the University of Syracuse; the money comes out of a \$25 million university research initiative at the Department of Defense that was to be used entirely for investigator-initiated, peer-reviewed grants for basic research.

Stephen Budiansky

West Germany

Support for biotechnology

Hamburg

By providing DM 1,000 million between 1985 and 1989, the Minister for Research and Technology, Heinz Riesenhuber (CDU), hopes to enable West Germany's biotechnological research to perform "jumps of perception" as chemical research did 150 years ago.

One principal task is to expand the Gesellschaft für Biotechnologische Forschung (GBF) into a national centre of biotechnology. Another is to promote the gene-centres in Cologne (plant cultivation), Heidelberg (immune defence, antibodies for cancer and rheumatism diagnosis) and Munich (chemical synthesis of nucleic acids) and to support two new centres for biotechnological process engineering.

Apart from financing basic research, Dr Riesenhuber, generally known as an obliging supporter of industrial research, plans to spend DM 120 million on a programme to further the biotechnological industry (*Programm zur Förderung der biotechnologischen Industrie*). Up to 40 per cent of expenses for projects will be refundable by the ministry up to a maximum of DM 600,000. This programme covers developments in cell and tissue culture techniques, genetic engineering, biotechnical procedures with human, animal and plant cells or manipulated microorganisms, new biological systems of plant protection and the use of enzymes in medical and food research.

Development of new apparatus and devices for biotechnological production will also be promoted in the new programme. Dr Riesenhuber is optimistic about the prospects.

The total value of biotechnological products in West Germany came to DM 17 million in 1983, compared with an estimated DM 40,000 million worldwide.

Bhopal

Birth defect fears allayed

New Delhi

ALTHOUGH there was an increase in the number of abortions, the gas leak tragedy in Bhopal last December did not result in the birth of handicapped babies as had been feared. Some 3,000 women were thought to be pregnant when methyl isocyanate (MIC) leaked from the Union Carbide pesticide factory on 2 December 1984, killing over 2,000 people. The Indian Council of Medical Research (ICMR), which has been following up 1,500 cases of pregnancy, says that by June, 500 babies had been born. Of these, five were born dead and three had congenital defects, an incidence statistically no higher than in a normal population. Most babies were low in birth weight (2 kg) but this too is not uncommon in India.

The rate of 17 abortions for 100 pregnancies was, however, above the national average. Dr V. Ramalingaswami, head of ICMR, says that this was not unexpected and that abortions increase by as much as four times during famine or epidemics, and the Bhopal tragedy was a comparable situation.

Soon after the accident, the state government of Madhya Pradesh considered compulsory termination of all pregnancies in the affected population. The proposal was dropped on the advice of ICMR which had no scientific data to warrant this step.

ICMR will, however, watch for any abnormality in the 1,000 babies expected to be born in the next two months from mothers who were in their first trimester of pregnancy at the time of the accident. "If MIC was really toxic to the fetus, it will be this group that needs watching", Dr Ramalingaswami said. According to his deputy, Dr S. Sriramachari, scattered anomalies in different organs would be a sure sign of MIC effect. But on the evidence so far, ICMR does not expect to find any anomalous births. In women yet to be delivered, ultrasonic scanning has shown fetal growth retardation in 15 per cent of cases, not unusual in India.

Meanwhile, ICMR has completed a health survey of 90,000 people, half the population that was exposed to MIC. Most are still undergoing treatments for respiratory and asthma-like problems, weakness of limbs and inability to carry on their usual work. Patients who had apparently recovered are said to be returning to clinics for recurring ailments. Some 1,200 patients are receiving injections of sodium thiosulphate (STS) which, according to Sriramachari, has been effective. STS is an antidote to cyanide poisoning but no one is sure why it works in MIC victims. It is possible that some MIC broke up into hydrogen cyanide when it escaped from the factory or that it produced cyanide radicals inside the body, after being inhaled. In any case,

ICMR's follow-up of STS-treated cases had revealed that STS mopped up the cyanide from the body and excreted it through the urine. ICMR is not sure how long to keep the patients on STS as they are found to develop symptoms once the injections are withdrawn.

While there has been no breakthrough in treatment, researchers claim to have obtained new information on the mechan-

ism of MIC poisoning. According to Sriramachari, analysis of blood samples from 60 cases has clearly shown that MIC attaches "to the terminal amino group of the alpha chain of the globulin part of the haemoglobin by a process of carbamylation".

This mechanism, he says, "explains the observed clinical features such as respiratory distress, associated with cherry-red venous blood, and toxicity due to failure of utilization and removal of CO₂ and consequently, deoxygenation".

K.S. Jayaraman

Eureka

Party launches agenda only

EUREKA, the French-led programme to unite European high-technology industry behind a handful of new products from driverless tractors to supercomputers, came into official existence on Wednesday last week. But exactly what Eureka is remains obscure, a situation that led the Paris newspaper *Le Monde* to comment that the decision was like film-maker Woody Allen's remark, "the answer is yes, but exactly what was the question?"

Nevertheless, officials present at the Paris meeting of ministers from 16 European states and the European commissioner for research count the broad agreement on Eureka a success. They point out that in the afternoon and evening allotted

We'll think of what it is soon...

to the discussion, there was hardly time for each delegation to make its own position statement, let alone to reach agreement on "points of detail".

Among the details not yet settled are the fundamental issues of who pays, how the programme is to be managed and on exactly what criteria projects are to be selected. The French President, M. François Mitterrand, put FF1,000 million (£82 million) on the table for 1986. West Germany made "ambiguous" noises about finding DM300 million (£75 million). But otherwise, there was silence from the 17 delegations.

There was, however, a frosty joke between Jacques Delors, president of the European Commission, and Roland Dumas, the French foreign minister. Delors, who has been put out by French insistence that Eureka should not fall into the hands of the "bureaucratic" Commission, has an ambitious technology programme of his own, and said he would

dearly like 20 per cent of national research and development budgets, to run joint European projects. Dumas replied that he would dearly like 20 per cent of the Commission's budget, to support Eureka. Stalemate.

Predictably, Britain was adamant that no special funding was required. Foreign Minister Geoffrey Howe claimed that Europe spends more on research and development than Japan, but gets less out of it. Therefore the problem was not one of research budgets but rather of opening markets. He therefore suggested, as part of a British package of projects for Eureka, that any products created through Eureka collaborations should receive what he described as "Eurotype" certificates — which should guarantee the product free passage through the many restrictive trade barriers that exist in Europe. This proposal is said to have been well received.

For now, the management structure of Eureka remains an open question, despite a strong play by France for a "small" office to be set up in Paris. Dumas said after the meeting that "some countries" had asked France to host the Eureka secretariat, but for the moment Eureka remains without a home.

In the brief final communiqué from Paris, the European Commission is described as acting "in strict consultation" with the Eureka action group. The communiqué also says that Delors' proposals "adopted" by the recent summit meeting in Milan will be "put into action", but what exactly this means will become clear only in future European Council meetings, but it must be doubted whether it will go anywhere near as far as the doubling of Brussels research budgets that has long been in the Commission's mind.

Otherwise, the communiqué says that "particular importance" will now be attached to "encouraging and stimulating the formulation of concrete projects among the industries and research centres of Europe", and to "conceiving the appropriate financial mechanisms". That is what everyone, industry included, is waiting for.

Robert Walgate

Poland

Environment at long-term risk

POLAND will need at least two decades of "huge social efforts and financial outlay" to restore an ecological balance that will satisfy the nation, according to Stefan Jarzebski, head of the Office of Environmental Protection and Water Economy. Presenting a report on the state of the environment over the past five years, Jarzebski told the Sejm (Parliament) last month that the losses caused by the degradation of the environment are now considerably greater than what is spent on attempting to counteract them. Decades of neglect of the environment have produced "calculable economic losses" — smaller crops, smaller yields of forest products, higher costs of water treatment for industry and domestic use.

A state inspectorate of environmental protection established in January 1980 has been insufficient, as the Sejm debate and resolution on the report made clear, to halt the deterioration of the environment. Since the law came into force, "extraordinary threats" to the environment have almost quadrupled, from 396 incidents in 1981 to 1,395 in 1984. Factories find it cheaper to pay fines for emitting pollutants than to take steps to eliminate the sources of pollution. (In 1984, almost 3,000 enterprises were fined a total of more than 2,500 million zloty.) Many important anti-pollution measures recommended under the 1980 law could not be put into practice, or even started, the Sejm noted, presumably as a result of the economic crisis. It should be noted, incidentally, that the closing of the Skawina aluminium refinery near Kraków in January 1981, an achievement to which Jarzebski attached great importance in his report, was not a government initiative at all. Demands to close the plant (which was discharging hydrogen fluoride into the atmosphere) came from the Kraków Ecological Club, one of the many private initiatives which sprang up in the wake of Solidarity, and which, with the backing of the Archbishop of Kraków, Cardinal Franciszek Macharski, managed to convince the relevant authorities that the cost of keeping the plant open, in terms of damage to the local environment and to the health of the population, was greater than the loss to the economy produced by closing it.

In spite of the closure of the Skawina plant, the Kraków area still remains one of Poland's black spots, the others being the Upper Silesian industrial belt (centred on Katowice), the Legnica-Głogów copper belt and the Gdańsk and Puck gulfs. Here, the Sejm decided, the deterioration may be classed as "ecological calamity". Twenty-three areas were designated as being at ecological risk. Even in the capital, Warsaw, householders have to boil their drinking water, and, in spite of this

precautionary measure, digestive disorders, urinary tract illness and cancer are on the increase.

The law of January 1980 was one of the few positive responses to environmental problems of the Gierek regime which tended to deal with such matters by censoring public discussion of them. The present government seems at least prepared to discuss them, perhaps because it has a ready-made excuse in Poland's continuing economic problems for any failure of delay in taking action. The Sejm's response to Jarzebski's data was to call for a national programme on the protection of the environment up to the year 2010, a plan which is expected to take at least two years to complete. In the meantime, "undertakings serving protection of the environ-

ment", says the Sejm, should be written into the 1986–90 Five Year Plan.

How far these recommendations will be accepted and implemented is, of course, a matter for the government and the industrial managers.

● Three leading Polish dissidents, Jacek Kuroń, Adam Michnik and Tadeusz Jędrzak suggested, last February, that independent Committees for the Protection of the Environment of Silesia should be established, the underground newsletter *Przegląd Wiadomości Agencyjnych* reported on 2 June. The report drew special attention to the high child death rate from cancer in Silesia due to the pollution of the environment, but noted that the majority of the population seemed unwilling to face the reality of the threat. No concrete action seems to have been taken on the proposal, and Michnik is now serving a prison sentence and Jędrzak awaiting trial on political charges.

Vera Rich

Soil Survey

Budget squeeze hurts projects

THE dwindling staff of the Soil Survey of England and Wales is still in the dark about its future. The unit, based at the Rothamsted Agricultural Station, will nevertheless have to decide by the end of October how many members of its staff will be retained beyond the beginning of the next financial year on 1 April 1986, when its budget will be cut in half.

The problems at the Soil Survey appear to be an almost classic illustration of how the Rothschild principle for research support can turn sour. The survey, formally established in 1939, and now constitutionally a part of the British Agricultural and Food Research Council (AFRC), has been supported since 1972 by research commissioned from the Ministry of Agriculture, Fisheries and Food, most recently (in 1983–84) to the tune of £1.8 million a year. In January this year, however, the ministry let it be known that the annual grant would be cut in half (to £850,000) in the year beginning next April. Nothing has been proposed for the succeeding year.

One inevitable consequence of this uncertainty is that the survey is losing staff. By the beginning of this year, largely because of declining research commissions, the staff at the survey had shrunk to 70 (from a peak of 85 in 1976); now it has fallen to 64, largely by allowing vacancies to go unfilled.

The decision about next year's budget was announced by Lord Belstead, an agriculture minister, in the House of Lords on 29 January, who explained that the objective of the reduced grant from next year was the British government's belief that "this is an area which ought to be commissioned by those who use the work". Much in that spirit, AFRC has commissioned a consultants' study of the opportunities for

persuading the Soil Survey's users to pay for the work it does. The report of that study, not yet formally presented, is understood to take the view that the survey could become self-supporting only on a smaller scale, but that a full 50 per cent reduction would not be needed.

The Soil Survey appears thus to be one of the first casualties of the work of the Agricultural Priorities Board, appointed a year ago to replace the previous Joint Consultative Organisation for agricultural research. Lord Belstead said last January that the decision to cut the budget of the Soil Survey had been taken after consultation with the board.

In the past few months, some outside contract work has come the way of the Soil Survey, which says it has been able to raise £175,000 to support certain aspects of its work. "That's six people's jobs for a year", one staff member said. Meanwhile, the pattern of the survey's work has been modified so as to concentrate on projects that could be rounded off by next year. For the time being, work on the 1:50,000 soil map of England and Wales, a project planned to be completed only in the 1990s, has been put on the back burner.

In principle, according to ministry sources, there is no reason why AFRC should not shoulder some of the burden of keeping the Soil Survey alive, although the council itself is under serious pressure from a reduction of its budget. The most likely help from the survey is some adjustment of the cost of premises at Rothamsted, now valued at some £350,000 a year. Paradoxically, nothing has yet been said about the comparable soil survey operation in Scotland, based at the Macaulay Institute, which was reduced by a fifth in 1982 but whose more distant fate will not be decided until the end of August. □

Pain and laboratory animals

SIR — The government's proposals to update the Cruelty to Animals Act 1876 (*Nature* 23 May, p.267) have been widely reported as tightening up the present deplorable situation, a view we strongly challenge.

On the question of pain, the government has proposed that the "severity" of an experiment should be balanced against its potential benefit. Three categories of severity are envisaged: mild, moderate and substantial. In addition, the government has set a "top severity limit" where "an animal which is in severe pain or distress which cannot be alleviated shall be immediately and painlessly killed".

Since it is impossible to devise a method of measuring pain in animals it follows that what may be considered "severe" pain or distress by one person may be dismissed as mild, moderate or substantial by another. Some government departments and officials share our view on this matter. For instance, the Home Office Departmental Committee of Inquiry on Experiments on Animals 1965 (the Littlewood Committee) concluded that "it is not as a rule possible to assess degrees of real pain in animals" (para. 187) and "it is often much more difficult to detect physical pain in an animal than in a human patient" (para. 174).

The subjective assessment of "severe" pain or distress renders such pain conditions meaningless to the animals, while at the same time allowing the government

and experimenters to pretend that there are permissible levels of pain, and that animals are thereby protected against excessive suffering. Furthermore, how is the importance of the experiment to be defined and does this refer to therapeutic, commercial or scientific considerations? Take for example the LD50 test in which animals are deliberately poisoned to death, which is clearly one of the most painful animal experiments. On the basis of the government's proposals, LD50 would have to fulfil a really important need, since the test causes so much suffering. But LD50 is generally recognized as bad science, so would the government refuse to allow the test to be performed? Or would the "severity" of LD50s be redefined as "moderate" or "mild" to overcome these difficulties? The latter course seems highly probable since the government has stated that it will not prohibit the LD50 test.

But the idea of prohibiting experiments, such as the use of animals to gain manual dexterity, is already established in the Cruelty to Animals Act 1876 and could readily be extended to other types of experiments, as a positive step towards a completely ethical system of research and health care.

Romanian reactors

SIR—We would like to provide some additional information on the Romanian nuclear programme (*Nature* 2 May, p.4). There is nothing misleading, as you put it, about our references to two plants now under construction in Romania.

The reactor civil works are well advanced on the first three units, the main excavation for the fourth unit has been started and site clearing has been commenced for the fifth. The office building and some of the permanent service buildings have already been completed and partly occupied.

The cooling water intake, pumping house is well advanced and the turbine foundations are reaching completion for the first and second units. The pipe fabrication shop, welder training and electrician shops are already in position.

In terms of manufacture, all the major orders have been placed. Babcock and Wilcox has already shipped heat exchangers and the first calandria or reactor vessel, the largest single component, is scheduled to be shipped from Canada before the end of this year. The arrangements between Atomic Energy of Canada Ltd (AECL) and the Romanians are that AECL will provide licence information so

that the Romanians can undertake a significant amount of the work themselves on the subsequent units.

The drawings and specifications have been delivered to the Romanians and they have a large engineering and drafting team of around 1,000 key staff who are now fully familiar with the engineering details of the CANDU reactor.

The fuel manufacturing shops in Romania have been completed and fuel is being manufactured and stored.

Commitment to the programme is evident to the highest levels in Romania, and this was obvious at the recent visit of President Nicolae Ceausescu to Canada. It included a tour of the Gentilly CANDU Nuclear Power Plant during which Mr Ceausescu entered the containment building and inspected some of the components while the reactor was at full power. He also reviewed the Romanian plans to commit further units and stated that the site for the next five reactors would be chosen before the end of this year.

The nose knows

SIR — Once again Gaylarde has taken it upon himself to "summarize briefly" my hypothesis (*Nature* 315, 92; 1985), and once again I must urge interested readers to read the original instead (*Nature* 311, 515; 1984). It is true that "the inhabitants of the dry desert regions of North Africa and the Middle East, where natural conditions provide the most viscous air to be found on Earth, are not noted for short notes with wide nostrils", but this is not evidence of a lack of effect from climate. People in hot dry places have had to adapt to dust, because hot dry places produce dust more easily and because hot dry air supports more dust. More properly, dry particles float in dry air while humid particles (humidity gained from humid air) sink. That is why people in dusty climates have dust-trapping noses.

Regarding the irrelevance of Gaylarde's advertised "familial virtue", I only wish to be clear that I do not claim familial virtue, or even personal virtue. I claim to have made an argument which is logical and empirically reasonable. Gaylard has decided that I am either a fascist or a would-be fascist (*Nature* 313, 425; 1985 and see also *Nature* 314, 398; 1985). I would prefer to hear his thoughts about my argument, but it seems that he will never calm down enough to get it straight.

Safety cabinets

SIR — In commenting on the relevant advantages of Class I and Class II safety cabinets (20 June, p.626), R. P. Clark deals only with the containment of aerosols. Much of my 40-year professional career as a medical microbiologist has involved work with high-risk pathogens including smallpox, lassa fever and simian B virus, and I have used all three classes of cabinets for this work. My experience leads me to say that for any pathogen in which the risk to the operator arises mainly from needle-stick type of injuries, Class II cabinets afford a significantly higher level of protection than Class I simply because of the better visibility which they afford and the better ergonomic design which is possible for Class II cabinets.

In my view it would be irresponsible to work in a Class I cabinet if a Class II cabinet was available, for this type of work.

Why celebrate laser birthday?

Lasers were first constructed 25 years ago. An historical account and some recent work appear in this issue. There can hardly ever have been an instrument that so quickly became pervasive.

WHY celebrate the 25th anniversary of the invention of a scientific instrument, the laser? Why not instead be patient, and wait for the more conventional half-century? Or, since lasers are mostly tools rather than objects of interest in their own right, why not celebrate the discoveries their existence has made possible rather than the means by which these ends have been successfully attained? These questions are all properly provoked by the group of articles on pages 307 to 330 of this issue. What follows is the explanation.

First, the supposition that lasers are merely tools for doing an admittedly huge diversity of jobs is easily made but is also false. With all that has happened in the past 25 years, it tends to be forgotten that the development of the first working laser was also the first occasion on which it became possible to study coherent electromagnetic radiation at or near the wavelength of visible light. By contrast, the study of coherent microwave radiation was in no sense dependent on the earlier invention of the microwave analogue of the laser, called the maser.

Both devices were also, as it happens, in their time the most vivid practical demonstrations of the reality of the phenomenon, originally inferred by Einstein during the development of his quantum theory of radiation (in 1912), that an excited atom capable of emitting a photon of a certain frequency will be stimulated to do so by radiation of that frequency or something like it, and that the likelihood of stimulated emission will be proportional to the intensity of the stimulating radiation. Although there was never any reason to quibble about Einstein's conclusion, which was enthusiastically used in the 1920s by R.H. Fowler and A.S. Eddington (for example) for the calculation of the transmission of radiation through stellar atmospheres, and although the direct calculation of the Einstein coefficient became one of the first successes of the wave mechanics of 1926, it always helps to turn a phenomenon into a fact of life that there should be a direct demonstration of it.

The device constructors now have an open licence. Their objective seems simply to make every possible kind of electronic excitation into the working principle of a laser, whence the emergence of solid-state semiconductor lasers (where the excitation is that of electrons into the conduction band). The outcome is coherent radiation because the stimulated emission

is always in phase with that which stimulates it. The practical difficulties are always those of producing a sufficient supply of excited entities, electrons in atoms or in semiconductors, to swamp incoherent spontaneous emission of the same radiation. So pumping (from the ground state to the excited state) is where the designers spend their energy.

Weird and wonderful things are done in the process, as shown by an account in the current issue of *Applied Physics Letters* of an attempt by R.S. Taylor and K.E. Leopold of the National Research Council of Canada to extend the pulse-length of a xenon/chlorine excimer laser (*Appl. Phys. Lett.* 47, 81; 1985). Here the excited state is that of an ionized atom, the lower level is a loosely-bound outer electronic state and the energy difference corresponds to ultraviolet radiation. Pumping such a device entails the creation of free electrons, which means an electric discharge.

But how can such a phenomenon be sustained for a reasonable length of time, say a microsecond? The answer offered is a double bank of capacitors discharging through one half of a rudimentary transformer, one quickly (in a few tens of nanoseconds) at high voltage and the other more slowly, through the laser gas made electrically conducting by the trigger pulse. The engineering of this equipment entails arguments of the kind now most commonly encountered among those who organize the discharge of the energy of capacitors into the plasma contents of thermonuclear fusion machines (but the laser is on a much smaller scale).

Taylor and Leopold claim an efficiency of 2 per cent for their device, with a 0.4 microsecond pulse of ultraviolet radiation, and indeed look forward to the continuous operation of devices like theirs. The US Strategic Defense Initiative will be interested. Taylor and Leopold calculate that they have extracted 1.5 J of power from each litre of lasing gas in a pulse lasting only 0.4 microseconds, which corresponds to 3.75 MW at continuous operation. Pumping the materials from which X-ray lasers may be made has still some way to go.

These are the practical problems; what are the benefits? Even after so short a time as 25 years, it is easy to overlook, or to take for granted, the way in which the use of lasers has transformed whole areas of investigation. Chemists concerned with the mechanisms of chemical reactions

were among the first to appreciate the value of devices that could be used to excite molecules in specific ways and in times short compared with those of chemical transformations and interactions. One tangible outcome, for example, has been a knowledge of the role of molecules of chlorophyll in photosynthesis that was previously entirely inaccessible. Similarly, there is now a whole new field of spectroscopy, that of the highly excited atoms called Rydberg atoms, whose existence has been made possible only by the availability of tools that can be used in the preparation of the Rydberg states. The value of being able to make measurements of the properties of the species involved in, say, the upper atmosphere or in stellar atmospheres should be huge.

The most casual readers of the literature must now be aware of the pervasive influence of lasers in most fields of research. (The issue of *Applied Physics Letters* carrying the article by Taylor and Leopold has no fewer than eight other accounts of schemes for making novel lasers function, but the journal is the device-constructor's running commentary.) Recent demonstrations that lasers, by means of the momentum transferred in the absorption of photons, can be used to rob atoms of virtually all their translational velocity ("cooling" is the term) points the way to a further increase in the accuracy of atomic spectroscopy and thus to the definition of frequency standards, or time standards, more accurate than even those now used (see B.W. Petley, *News and Views* 27 June, p.716).

It is also now a matter of common knowledge that the stability of certain geological structures, critical parts of the San Andreas fault, for example, are monitored by geodetic lasers, that other instruments are used for the direct measurement from the ground of the constituents of the upper atmosphere (LIDAR) and that the accumulation of data from Earth satellites and from the corner reflectors left on the Moon during the Apollo missions will eventually yield a more precise test of current understanding of the dynamics of the Solar System, relativistic corrections included.

So there is plenty to celebrate. That lasers would turn out to have such an influence in so many different fields was foreseen 25 years ago. The surprise is that so much has happened so quickly.

John Maddox

Muscle contraction

Weak and strong crossbridges

from Malcolm Irving

IN THE most widely accepted model of muscle contraction the actin filaments are pulled along by the cyclical action of crossbridges projecting from the myosin filaments. In this model, crossbridges are thought to attach to actin roughly at right angles to the filament axis (the so-called 90° state) and then to swing round in a power stroke that moves the actin filament by about 120 Å (refs 1,2). Binding of ATP is believed to cause detachment of the crossbridge, the ATP has to be hydrolysed before the crossbridge can rebind to actin and repeat the cycle³. This model was an attractively simple explanation of mechanochemical coupling in muscle. But it is now being suggested that crossbridge detachment is not an obligatory consequence of ATP binding⁴, that the idea of the 90° state needs major revision^{4,5} and that the power stroke is much shorter than 120 Å (ref.5). In contrast, T. Yanagida *et al.* elsewhere in this issue⁶ present an argument for a power stroke larger than 600 Å (see box). Where does this leave the crossbridge theory?

A cartoon of the original model is shown in Fig.1, where the crossbridge is drawn as a 'ball-on-a-stick'. The elongated ball is the 'head' domain of myosin (M), containing the ATP and actin binding sites. Starting at the lower left of the reaction cycle, a head with bound ADP and phosphate (P) binds to actin (A) to produce the complex AM.ADP.P_i. Release of the products of ATP hydrolysis is coupled with the power stroke as the head swings to 45° (AM). ATP binding detaches the head (M.ATP) from actin, the ATP is hydrolysed and the resulting complex, M.ADP.P_i, can rebind to actin in the 90° configuration. This biochemical scheme was suggested by studies in solution on the interaction of actin with isolated myosin heads⁷.

E. Eisenberg and T.L. Hill⁸ have recently reviewed these solution studies in the light of subsequent experiments using a wider range of conditions, it is now clear that, in solution, ATP binding to the head does not necessarily cause it to dissociate from actin before the ATP is hydrolysed. Rather, when either ATP or ADP and P_i are on the head it is weakly bound to actin, in a rapid equilibrium between attachment and detachment. A simple crossbridge cycle suggested by these newer data is shown in Fig. 2. Here there is no structural difference between the weakly bound AM.ATP and AM.ADP.P_i complexes, which have been depicted with a range of orientations to suggest the possibility that they do not have a sterically unique conformation. The power stroke is still associated with P_i release, and drives

the head into the strongly bound AM.ADP and AM states. The difference is that ATP binding now returns the head to the weak binding states rather than detaching it.

At first sight the new model seems to have a fundamental defect: the power stroke is reversed while the heads are still

attached, which must push the actin filaments the wrong way. Why does this not reverse the work done in the power stroke? Recall that a myosin filament has many crossbridges working in parallel, but asynchronously, so that swinging of an individual head will not necessarily be accompanied by movement of the actin

filament to which it is attached. The difference must be taken up as conformational strain within the attached bridge. To make the model work, Eisenberg and Hill propose that those heads in the population that are strained the 'wrong' way detach more quickly. The general idea of a strain-dependent detachment rate is not new⁹ and, indeed, is necessary for the efficient operation of any model of this general type, including that in Fig. 1. Such models can provide a quantitative description of the mechanical and energetic properties of muscle¹⁰, but are not critically dependent on the chemical identity of the intermediates in the crossbridge cycle.

Does the biochemical cycle in Fig.2, inferred from solution studies, actually occur in contracting muscle? The answer will require biochemical studies of intact muscle fibres, in which it is difficult to apply the transient kinetic techniques used in solution. Fortunately, it has recently become possible rapidly to release ATP from a photolysable precursor inside muscle fibres¹⁰, providing at least a partial solution to the technical problem.

From the structural viewpoint the model in Fig. 2 is rather poorly defined. One general problem is that if strain in a crossbridge affects its structure then a given biochemical state may not be identifiable with a unique conformation. Nevertheless, there still might be two types of conformation corresponding to the strongly and weakly bound states. H.E. Huxley and M. Kress¹¹ have now summarized the ultrastructural evidence from contracting muscle and demonstrate

A crossbridge too far ?

AN interesting new view of the crossbridge power stroke is presented by T. Yanagida, T. Arata and F. Oosawa on page 366 of this issue. They have estimated the length of the power stroke from the maximum velocity of filament sliding in crab muscle, in which the sarcomeres are long enough for the velocity of fluorescently labelled actin filaments to be measured with a light microscope. The normal transverse connection between adjacent actin filaments — the Z line — was removed by selective proteolysis, leaving single sarcomeres with a normal array of myosin filaments but with actin filaments that were now free to move independently. On addition of ATP in the presence of calcium, all the actin filaments started to slide with a velocity of about 5 $\mu\text{m s}^{-1}$. The rate of ATP hydrolysis in the same conditions was about 1 s^{-1} per myosin molecule, which corresponds to about 80 s^{-1} per actin filament.

Yanagida and his colleagues argue that as viscous drag would very quickly attenuate actin filament momentum, each filament must have at least one crossbridge pulling on it at any instant. So if one ATP molecule is hydrolysed per crossbridge cycle, the rate of cycling of active cross-

bridges could not be higher than 80 s^{-1} . To achieve a filament velocity of 5 $\mu\text{m s}^{-1}$ the length of the power stroke under these conditions would therefore have to be at least 5/80 μm or 625 Å.

This estimate is not only strikingly larger than those obtained by other methods (see accompanying article) but also than the largest dimension of the crossbridge head (190 Å) or the actin monomer (70 Å). If the power stroke really is greater than 600 Å, some drastic rethinking of the swinging head crossbridge model would be required. The paradox might be most simply resolved, and a short power stroke retained, if the condition that one ATP molecule must be hydrolysed per cycle of crossbridge attachment and detachment did not hold during rapid filament sliding against little or no resistive force. This could occur, for example, if the number of weakly bound, rapidly attaching and detaching crossbridges increased during sliding as the degree of overlap between actin and myosin filaments became progressively greater. This might make sliding energetically favourable without committing such crossbridges to ATP hydrolysis.

Malcolm Irving

that it is consistent with the existence of two such populations.

Strongly bound crossbridges may be structurally similar to those in rigor muscle, where no ATP is present. If such heads were attached to actin in a stereospecific way and all had the same shape they would take up the periodicity of the actin filament helix. X-ray diffraction studies suggest that no more than 20 per cent of the heads are attached in this way during contraction (compared with 100 per cent in rigor). This is marginally consistent with electron spin resonance studies¹¹, which indicate that in about 20 per cent of the crossbridge heads the probed domain has the same orientation as in rigor; the rest of the heads are disordered and rapidly mobile. However, another part of the X-ray diffraction pattern shows that at least 60 per cent of the heads are near the actin filaments during contraction. Huxley and Kress suggest that in addition to the 20 per cent of strongly bound heads, a further 40 per cent are weakly bound, with a wide range of permitted orientations and in a rapid equilibrium of attachment and detachment. Independent evidence for this type of crossbridge attachment has come from studies on demembrated muscle fibres in calcium-free, low ionic strength media — conditions in which isolated heads in solution are weakly bound to actin. X-ray diffraction studies on such fibres showed that the crossbridges were near actin but had not taken up its helical periodicity¹² and, although no force is generated, mechanical studies detected a population of rapidly attaching and detaching crossbridges¹³.

Do the weakly bound crossbridges in contracting muscle also generate no force? If only the strongly bound 20 per cent of heads do so, one can calculate that each would have to exert about 6 piconewtons in a slowly shortening muscle. But if this is applied over a 120 Å power stroke the work produced per cycle (7.2×10^{20} joules) would be about three times greater than expected from ATP hydrolysis on the basis of the observed macroscopic efficiency. Huxley and Kress conclude from a similar calculation that if only 20 per cent of heads produce force the power stroke must be smaller than originally proposed — they suggest it is about 40 Å. The previously favoured value of 120 Å came from experiments in which extremely rapid shortening was imposed on active muscle²; fast force recovery was seen only if the filament sliding was less than 120 Å. Huxley and Kress suggest an alternative interpretation of these experiments in which 120 Å becomes the range of attachment of the weakly bound heads. Although these would not normally be force producing, filament sliding of up to 120 Å would bring them into the force-generating zone where they could make the transition to the strongly bound state. A 40 Å power stroke of a strongly bound head could plausibly occur in an all-or-

none fashion, storing energy in the conformational strain of another part of the crossbridge. This would explain why the ordered heads in contracting muscle have exactly the rigor conformation (as detected by spin-resonance probes): strongly bound heads are only seen at the end of their power stroke.

Many questions remain. Much of the mechanical and structural data could be explained without postulating the existence of weakly bound, non-force-generating crossbridges in contracting muscle. In an alternative view most of the heads would be strongly bound, force generating and take up a wide range of conformations with rapid transitions between them². A key proposal of the model of Huxley and Kress, that only 20 per cent of heads are strongly bound and force generating, derives from studies with extrinsic probe molecules. It will be important to check by independent methods that crossbridge properties have not been modified by the probes and that the mobil-

ity of the probe does indeed reflect that of the head. This proposal also seems difficult to reconcile with existing data from experiments designed to compare the mechanical properties of contracting with rigor muscle¹⁴ which suggest that the fraction of force-generating heads during contraction may be as high as 75 per cent. Nevertheless, the idea that there are two types of crossbridge in contracting muscle — weakly and strongly bound — provides a neat and stimulating synthesis of a wide range of muscle phenomena. In the longer term its success will depend on the extent to which these two hypothetical states stand up to attempts at making a more rigorous characterization of their structural and dynamic properties. □

Structural geology

To stretch a continent

from I. R. Vann

THAT large areas of the Earth's crust have been subjected to compression has been known since before the discovery of plate tectonics. But, outside the world of hydrocarbon exploration, extensional tectonics has been a topic of intensive study for less than a decade. A recent conference* illustrated the remarkable progress that has arisen from two very different scientific approaches, the first a deduction straight from the world of physics, the other an induction rooted firmly in the geological tradition of careful field observation.

Seven years ago, D. McKenzie made what in retrospect seems a trivially simple prediction (*Earth. planet. Sci. Lett.* **40**, 25; 1978) — if the lithosphere is stretched then it must thin. Since the base of the lithosphere is an isotherm, a thermal anomaly is created that slowly decays causing subsidence of the crust as an inverse exponential function of time. The

power of this model is that it connects the stratigraphy and thermal history of the sediments filling a basin with a regional structure. At around the same time, field studies in the 'Basin and Range', the core of the Rocky Mountains of the western United States, began to show that the structure of the area is dominated by flat-lying extensional faults (detachments) with horizontal offsets across them of tens of kilometres.

This observation dispelled an old geological prejudice that sub-horizontal faults are all compressional structures (thrusts). Despite this a number of questions remain, concerning the original geometry of the flat detachments, the relevance of the Basin and Range model to other extensional basins and the relationship between the extension recorded near to the surface in rift basins and deeper structures.

At the conference the problems of unraveling the original geometries of flat detachments was exemplified by the con-

*'Continental Extensional Tectonics', University of Durham, UK, 18-20 April 1985

tributions of G. H. Davis (University of Arizona), and E. L. Miller (Stanford University) and her co-workers. Davis suggested that the faults and the 'metamorphic core complexes' that underlie them were originally moderately dipping ductile zones of simple shear formed at 10 km or deeper within the crust. As extension progressed, the material overlying those 'faults' was moved laterally by tens of kilometres. The overall effect of this is to bring the faults nearer the surface and thus reduce the confining pressure and temperature. This causes a change in the deformation from a ductile to an increasingly brittle process. According to Davis, younger cross-cutting extension faults later rotated the dipping zones to horizontal.

E. L. Miller's model is markedly different. She suggested that the Snake Range detachments in Nevada are neither faults nor shear zones but the transition, formed at a depth of 12 km, between an upper brittle plate and a lower ductile one, which latter deformed by pure shear expressed as horizontal extension and vertical thinning. Many other speakers accepted in modified form one or other of these apparently incompatible models but it was disconcerting for the outsider to see that this marvellously exposed area remains so enigmatic.

Even if the Basin and Range ultimately yields a single unified model it will remain a unique area of extreme extension within a region of relatively recent crustal thickening in the core of a thrust mountain belt. A possible ancient analogue — the Devonian (380 Myr old) basins of western Norway — was described by M. Seranne, M. Seguret and Ph. Laurent (University of Montpellier II). Here 50 km or more of extension occurs above a shear zone, apparently a reactivated thrust, which dips westwards at 5° to 25°, thereby creating a basin containing sediments up to 25 km thick. Geometrically similar basins, observed on deep seismic profiles (Brewer, J. A. & Smythe, D. K. *J. geol. Soc. Lond.* 141, 105; 1984), occur above similarly reactivated thrusts on the western margin of the Caledonian mountain belt in north-west Scotland, which appear to flatten as they enter the lower crust at a depth of around 18 km. These fragmentary observations suggest that an extensional province similar to the Basin and Range existed within the Caledonian mountains some 380 Myr ago.

Is it possible to carry the Basin and Range analogy further? Certainly there are great differences between the extension within mountain belts and that which creates great sedimentary basins (rifts) in old stable crust (such as the East African Rift). Perhaps the most obvious of these differences is that almost all these rifts are covered by water or thick blankets of sediment. Hence their structure is not accessible to the geologist's hammer and our understanding depends largely on seismic

reflection data that are even more ambiguous than surface observation. A. D. Gibbs (Midland Valley Exploration, Glasgow) presented models of rift fault systems developed in the North Sea that exemplify the belief of a growing number of workers that extension is achieved by movement on a linked series of faults that have flatter and steeper portions producing a 'staircase' geometry in the upper crust. These faults systems are strongly asymmetric giving rise to basins bounded on one side only by major faults. Along the length of any basin this asymmetry flips from side to side across complex transfer zones.

Unfortunately the seismic data, which has been acquired almost exclusively by oil companies, images only the upper 10 km of the crust. Basin and Range models are applicable, if at all, to rift systems at depths of more than 15 km where it is thought that the crust changes from a generally brittle to a ductile material. Evidence about deformation at these depths below rifts comes from a very few deep reflection experiments conducted mainly on the UK continental shelf. A. Beach (Britoil, Glasgow) presented one such profile across the northern North Sea. His interpretation suggests two major periods of extension in this rift with active faulting in Triassic and early Jurassic times (220–200 Myr) above a single low-angle shear zone akin to the Basin and Range model

of G. Davis being followed by extension at the end of the Jurassic along steep faults that cut entirely through the crust. The profile demonstrates that the crust below the rift is only half as thick as it is on the flanks and hence supplies one of the few direct tests of the McKenzie stretching model.

Support for Miller's interpretation of the Basin and Range came from a discussion by J. A. Jackson (Cambridge University) of deep deformation processes within active regions of extension. He noted that all major earthquakes in active regions occur on faults dipping at 30–60° at depths of 8–12 km and are grossly planar from the surface to these depths. Below this earthquakes are rare, but when they do occur (usually as aftershocks to large shallower events) they seem to do so on horizontal fault planes. Jackson concludes that extension in the lower crust normally takes place by ductile diffuse creep with only minor brittle effects.

Despite unanswered fundamental questions, and amidst much conflicting evidence and irreconcilable theory, many participants left the conference feeling that they had attended an important event. Among the conflict it seems there is a convergence that in a very few years will lead to a unifying 'general theory' of extensional tectonics. □

Infrared astronomy

Views across the Galaxy

from Charles Beichman

No longer the coveted property of just a few infrared astronomers, the wealth of data returned from the Infrared Astronomical Satellite (IRAS) is now being studied by a large number of scientists working in all regions of the spectrum. Three days of a recent conference* were devoted to the presentation and discussion of IRAS discoveries within our Galaxy. More than a dozen invited talks and fifty contributed papers described what IRAS has revealed about the death and birth of stars, the large-scale structure of the Galaxy and properties of interstellar dust.

An examination of the overall statistics of the IRAS point source catalogue (T. Chester, California Institute of Technology) demonstrates the importance of IRAS to galactic astronomy. Half of the 245,839 sources detected by IRAS lie within seven degrees of the galactic plane; two thirds of the sources lie within the central two quadrants of the Galaxy. Roughly 158,000 stars within the Galaxy comprise 65 per cent of the catalogue. Some 65,000 objects are associated with different phases of the interstellar

medium, including H II regions, molecular clouds with embedded pre-main sequence stars and dense clumps of cold dust. The remaining 9 per cent of the catalogue consists of about 22,000 external galaxies. Spectroscopic data obtained with the IRAS Low Resolution Spectrometer are available for the 5,000 brightest objects (F. Oloin, Groningen).

At the end of its life, a normal star ejects a large part of its mass back into interstellar space. The resulting shells of circumstellar dust can convert most of a star's luminosity into infrared energy and make such stars detectable by IRAS across nearly the entire Galaxy. H. Habing (Leiden) used stars with shells detected at 12 and 25 microns to trace the disk and central bulge of the Galaxy with unprecedented clarity (see figure), free from the effects of inter-

*The IRAS Symposium "Light on Dark Matter" was held at Noordwijk aan Zee, the Netherlands, 10–14 June 1985.

stellar extinction that preclude such studies at visual wavelengths. The colours and luminosity of these stars resemble those of previously known OH/IR stars, which, in addition to being bright in the infrared, emit intense radiofrequency radiation in the spectral lines of the OH radical. Ground-based observations (J. Frogel, Kitt Peak; M. Feast, South African Observatory) confirm that many IRAS stars found in the bulge are late-type M giant stars, with luminosities as large as 10^3 to $10^4 L_{\odot}$, that are losing mass at a rate of 10^{-6} to 10^{-4} solar masses per year. The age of these stars and the mass of their main sequence progenitors are quite uncertain, but an intriguing possibility is that they were originally one-solar-mass stars and are no more than a few billion years old, far less than the age of the Galaxy. In that case, there may have been a burst of star formation in the bulge of the Galaxy that resembled bursts seen towards other infrared-bright galaxies detected by IRAS.

B. Zuckerman (University of California, Los Angeles) gave two reasons why an understanding of the mass loss in these late-type stars is important. First, as we observe many white dwarf stars and relatively few supernovae in the Galaxy, mass loss must provide the mechanism whereby stars more massive than 1.4 solar masses lose enough material to avoid a catastrophic demise when their nuclear fuel has been consumed. Second, it is through mass loss that the carbon, nitrogen and oxygen produced by nuclear burning are injected into the interstellar medium for subsequent processing into new stars, planets and, eventually, astronomers. By using a combination of IRAS measurements and millimetre-wavelength observations of gas outflows for a large sample of IRAS stars, it will be possible to learn much about the dynamics and chemistry of the mass-loss process and its relation to later stages of stellar evolution.

P. Bedijn (Heidelberg) explained the cause of mass loss in terms of a positive feedback mechanism coupled to global pulsations of the star. His theory derived support from the fact that more than half of the IRAS sources varied in brightness by as much as a factor of three over the course of the IRAS mission.

After the mass-loss phase ends, it is thought that late-type giants become planetary nebulae which consist of a 50,000 K star surrounded by a thin shell of ionized gas. A. Leene and S. Pottasch (Leiden) used 8 to 22-micron spectra obtained with the Low Resolution Spectrometer to show that for some of the more than 700 planetaries detected by IRAS, the radiation does not come from hot dust, but rather from spectral lines from ionized gas. Emission from spectral lines of S IV (triply ionized sulphur), Ne II, O IV and S III account for all of the radiation detected by IRAS in the 12- and 25-micron bands of the survey. Leene and

Pottasch predicted that lines of N II and O III could account for some or all of the 60- and 100-micron radiation detected in the survey for these objects. IRAS maps of planetary nebulae can be used to examine the temperature, abundance, density and excitation of these ionized species.

IRAS is also well suited to studying the other extreme of the life history of stars — their birth out of the interstellar medium. The physics of star formation represents a fundamental problem in modern astronomy which is relevant both to the structure of our own Galaxy as well as to the energy production mechanisms for the most luminous starburst galaxies detected by IRAS. As B. Elmegreen (IBM, T.J. Watson Center) pointed out, IRAS data at the highest sensitivity and spatial resolution can be used to study the detailed physics of star formation, and IRAS images can be used to study large-scale processes in the interstellar medium that produce stars.

One mechanism for the formation of stars that has been discussed for many years is that H II regions around newly formed massive O and B stars trigger the fragmentation and subsequent collapse into new stars of adjacent material in a giant molecular cloud. By examining the 60- and 100-micron images produced by IRAS, P. Schwartz (US Naval Research Laboratory) found circumstantial evidence for loops and rings of star formation surrounding earlier sites of star formation. One such loop is 250 pc in diameter and contains many H II regions and embedded young stars. If further examination of the IRAS images shows that star formation is often associated with structures of this type, then the case for triggered or sequential star formation will be greatly bolstered. As Schwartz emphasized, large-scale morphological studies of this kind are possible only with the advent of the IRAS images that present to the eye in a single picture both the distribution of the

interstellar matter and the presence of embedded young stars.

A second way by which star formation may proceed is to compress small globules of interstellar material enough to overcome the supporting motions within the cloud and so initiate a gravitational implosion that leads to the formation of one or more stars. It is possible that many solar-type stars form in this manner, rather than in the triggered fashion of the more massive stars. The existence of this more sedate and spontaneous type of star formation has been demonstrated by P. Myers (Center for Astrophysics), C. Beichman (California Institute of Technology), S. Harris and J. Emerson (Queen Mary College, London) and R. Jennings (University College, London) who examined more than 100 small clumps of interstellar gas in the Taurus and Ophiuchus molecular clouds, some 150 pc away. These clumps contain between 5 and 50 solar masses of material and represent the simplest possible sites for star formation. The IRAS survey shows that about half of these clouds are associated with infrared point sources. Although a few objects can be identified with visible pre-main sequence stars (T Tauri stars), the remainder have no visual counterparts. The invisible sources have very low colour temperatures, about 100 K, and luminosities of 0.5 – $10 L_{\odot}$. Although it is not possible to determine the masses of such objects accurately, it is likely that stars of about 0.5 – 1 solar mass are being formed in these clumps.

The most important, but as yet unanswered, question about these embedded infrared sources concerns their evolutionary status. Some of the invisible infrared objects are probably T Tauri-like stars, no older than 10^5 years, that obtain their energy from the slow contraction of a stellar core in quasi-static equilibrium, but which are still obscured from view by placental gas and dust. On statistical

100 years ago

MR TROMHOLT has rendered a great service to science by the travels and observations recorded in these volumes¹; indeed, it would not perhaps be going too far to say that we have here, brought before us in the most interesting manner, one of the best organised attempts to study the aurora that has been made for many years, the credit for which must be given to the organisers of the International Polar Research Expedition of 1882–83. The results, however, recorded in these volumes are by no means limited to the height of the aurora. The con-

THE AURORA

stant study afforded to Mr. Tromholt of one of the most awe-inspiring phenomena which it is given to man to witness have permitted generalisations to be reached and hypotheses to be broached of the greatest scientific interest. Mr Tromholt holds that *the auroral zone moves northwards and southwards daily, yearly, and eleven yearly*. To speak in vacuum-tube language, instead of one rigid stria, we may have many striæ, and these moving towards or away from the auroral pole as ordinary striæ move towards or away from the negative pole.

¹Under the Rays of the Aurora Borealis. By S. Tromholt. Edited by Carl Siewers. (London: Sampson Low & Co., 1885.)

From *Nature* 37 274, 23 July 1885.

grounds, however, it is probable that some of these IRAS sources are still deriving most of their luminosity from the release of the gravitational energy of infalling cloud material. These objects can be considered to be true protostars. Confirmation of this status and further study must rely on observations at other wavelengths, in particular at high spatial and spectral resolution in the near-infrared and at millimetre wavelengths.

Infrared astronomy can be considered to be the study of dust in one form or another, and a large part of the conference reflected the importance of solid material, heated enough to be detectable in the infrared. The so-called infrared cirrus, diffuse emission from interstellar dust, is an important and puzzling discovery of IRAS. T. N. Gautier (California Institute of Technology) and others showed that at 100 microns the cirrus can be correlated with faint dust features visible on high-contrast optical photographs and with structures seen in 21-cm maps of atomic hydrogen (H I). Some cirrus can be associated with weak emission seen in high galactic molecular clouds.

Some of the most exciting results concern the diffuse emission seen at 12 microns by IRAS. The properties of 12-micron cirrus tend to confirm the work of K. Sellgren (Hawaii) that there exists dust whose apparent colour temperature is much hotter than its equilibrium temperature. The explanation of this effect is that motes of dust a few tens of angstroms in size can be heated, briefly, by the absorption of a single ultraviolet photon. The heated grains cool off by emitting radiation at anomalously hot temperatures. A. Leger, J. L. Puget and F. Boulanger (Paris) have identified polycyclic aromatic hydrocarbons as a likely type of grain material. Composed of carbon and hyd-

rogen ions, they are not only stable at the small sizes required, but also have spectral features at 3 and 11 microns that match previously unidentified bands found towards several infrared sources.

The realization that very small grains play an important role in the interstellar medium was brought out repeatedly during the conference. Elmegreen pointed out that if very small grains exist at the centres of dense molecular clouds and not just at their periphery, then they will be charged and will control the coupling of the gas to the magnetic field. The properties and abundance of these grains may control the collapse of molecular clouds.

The 60- and 100-micron IRAS maps have been used to examine the large-scale structure of the interstellar matter in the Galaxy. B. Burton, H. Walker and E. Deul (Leiden) found that the scale height of the 100-micron emission is about 120 pc, the same as that of the atomic hydrogen (H I), and twice as great as the scale height of the molecular gas as inferred from CO observations. Thus, IRAS has traced the distribution of warm (22 K) dust in relatively diffuse regions and not the distribution of the colder, denser material. A longer wavelength map of the Galaxy, say at 200–300 microns, would trace the 10–15 K material associated with the molecular component of the Galaxy.

The IRAS catalogue and all sky images have been generally available only since last December. The number and variety of results reported at the conference suggest that the data returned by IRAS will be a valuable resource for astronomers for years to come. □

Infrared astronomy

Views outside the Galaxy

from Martin Ward

ALTHOUGH the infrared satellite mission IRAS ended its life more than a year and half ago, its influence on the subject of infrared astronomy promises to continue for many years to come, by virtue of the enormous database of observations that it produced. That this is so for extragalactic astronomy was demonstrated at a recent workshop*, the main thrust of which was aimed at the understanding of aspects of star formation within galaxies.

Young stars are hot and emit most of their energy in the optical and ultraviolet regions of the spectrum. But as dust and gas exist together in the star-forming regions, some of these optical and ultraviolet photons heat up the dust grains,

which then radiate approximately like black bodies. The exact temperature of the heated dust will depend on various factors but, leaving aside the more exotic active galactic nuclei for the moment, the range extends from 30 to 100 K. These temperatures produce peak emission in the infrared, hence the connection between star formation and far-infrared emission.

As was emphasized by H. Yorke (University of Göttingen), there are still fundamental questions that need to be answered concerning star formation and the evolution of H II regions. For example, relatively how many new stars of various masses are formed in any one episode of star formation? Since high mass stars evolve faster than those of low mass,

the differences in relative numbers will manifest themselves as changes with time in the integrated properties of the burst of star formation ('starburst').

There are several ways in which the efficiency of star formation may be related to large scale morphological properties of galaxies—another fundamental problem. For example, T. Harwarden (Royal Observatory, Edinburgh) suggested that the presence of galactic bars may provide a kinematic catalyst which channels material inward to sites of galactic nuclear starbursts. An obstacle to progress in this area is the sheer difficulty of quantifying objectively the pictorial evidence of bar structure. Another process that may enhance the efficiency of, and/or provide a trigger mechanism for, a burst of star formation is that of galaxy interactions. R. Joseph and co-workers (Imperial College, London) have surveyed interacting pairs of galaxies and find evidence for starbursts to be very common, although characteristically only in one member of a pair.

The key observational inputs to star formation models were discussed by C. Telesco (NASA Marshall Space Flight Center). An important parameter is the total infrared luminosity of a star-forming region which, roughly speaking, indicates the number of young stars present. For this purpose the IRAS observations are ideal, covering as they do a range of 12 to 100 microns. Another global property is the mass/light ratio. In the conventional units normalized to the solar values it is known that an old stellar population has a ratio of greater than three, whereas it is predicted that the ratio for an unevolved stellar population (formed with the mass distribution observed in the solar neighbourhood) is less than 0.01. This index can therefore be used as a measure of the age of the stellar population and hence of the presence and strength of a starburst. Telesco described the application of a starburst model to the famous galaxy Messier 82. The implied age of the starburst in M82 turns out to be 20 million years. Using the far infrared luminosity, the deduced rate of star formation is 34 solar masses per year which, integrated over the age of the starburst, is a large fraction of the total mass. To avoid the situation in which such a large fraction of all mass has been converted, it is necessary to impose a cut-off in the mass distribution of the new stars. Thus, in luminous starbursts there would be relatively few new low-mass stars, high-mass conversion rates and short-burst durations. These findings will have important implications for models which follow the evolution of starbursts.

The blue compact galaxies, also known as extragalactic H II regions, are relatively unevolved stellar systems. Their near-infrared colours indicate that they are young and/or metal-deficient, meaning that relatively little mass has been converted into heavier elements via stellar evolution. In support of this, IRAS obser-

* The meeting on Extragalactic Infrared Astronomy was held at the Rutherford Appleton Laboratory, 20–27 May 1985.

variations show that the gas/dust ratio in such galaxies is a thousand times higher than that in the solar neighbourhood (P. Gondhalekar, Rutherford Appleton Laboratory); the most probable implication is that there is a pronounced paucity of dust. If dust is formed in stellar atmospheres, the low dust content implies either a slow rate or late start of star formation. It is still controversial as to whether we are witnessing the initial starburst or whether these galaxies have experienced a series of previous bursts.

Naturally the more exotic examples of active galaxies also received some attention. I reported new infrared results for an X-ray selected sample of Seyfert galaxies. Although there are exceptions, in most cases the dominant mechanism responsible for the strong infrared emission is not a massive burst of star formation such as observed in M82. It seems rather that the near infrared emission at a few microns is related, but not necessarily via the same physical process, to emission from the very compact regions. Good correlations are found with the strengths of the very broad emission lines and the X-ray emission, whilst at 20 microns the best correlation is with the narrow emission lines which originate in a volume of typically a thousand light years. This 20-micron luminosity could come from warm dust (200 K) mixed in with the line-emitting gas and heated by the very compact source at the centre of the active nucleus.

Because of the large apertures of the IRAS observations, their relation to the compact active nuclei in Seyfert galaxies is not clear. It seems probable that we are seeing a 'mixture' of several spatially-distinct components. Michael Rowan-Robinson (Queen Mary College, London) showed how, for Seyfert galaxies, the IRAS data can be separated into three

components: a cooler disc component (seen in more normal galaxies), a warmer starburst component and a Seyfert component peaking at 25 microns. The latter could be radiation from a mini-quasar at the centre of the Seyfert absorbed by dust and re-radiated in the infrared.

The cosmological implications of the IRAS observations were also considered by Rowan-Robinson. Concentrating on the galactic polar caps, where confusing effects of the infrared 'cirrus' (see *Nature News and Views* 308, 224; 1984) are smallest, he showed that there is a significant anisotropy in the number density of IRAS 60-micron sources between the north and south polar caps.

This seems not to be a local phenomenon since an identification programme carried out for the northern cap reveals that, after elimination of obvious stars, virtually every source is a galaxy and that the typical distance of IRAS galaxies is about 200 megaparsecs. Assuming that the infrared radiation traces the matter, it is possible to map the gravitational field and determine its dipole component. The direction of this component is in good agreement with the observed anisotropy in the intensity of the cosmic microwave background radiation. Thus this anisotropy could be explained as the result of the net gravitational pull on our local group of galaxies by the distribution of galaxies within about 200 megaparsecs.

Rowan-Robinson also showed that the 100-micron background radiation detected by IRAS can be separated into components due to interplanetary dust, interstellar dust and a roughly isotropic component which may be of cosmological origin. □

Solid-state chemistry

Topotaxy in metal-oxide reduction

from Robert W. Cahn

A THIN metal film deposited by evaporation or sputtering on, say, a cleavage surface of sodium chloride is apt to be oriented in a reproducible way with respect to the substrate — this is the commonly found physical process of epitaxy, where the substrate is inert and unaffected. The chemical analogue is a topotactic reaction¹: here a parent phase undergoes a reaction and the product phase has one or more defined orientations relative to the parent. Such reactions have been analysed by metallurgists (although they never use the term topotaxy) ever since the discovery of X-ray diffraction: the key investigations on so-called Widmanstätten reactions in metallic solid solutions were carried out in the early 1930s. Metallurgists usually analyse

such reactions in terms of the fit of parent and product phases at their mutual interface.

The reverse reaction, reduction of an oxide to metal, has occasionally been examined from a kinetic point of view, especially in connection with the industrially important reduction of wuestite (FeO) to iron², but the first study of topochemical aspects has only just been performed. The results, reported by A. Revcolevschi and G. Dhalenne on page 335 of this issue³, open up a new field of research.

In chemistry proper, topotaxy is usually demonstrated in dehydration reactions — for example, the conversion of Mg(OH)₂ into MgO — or the conversion of one oxide of iron into another; other instances include breakdown of complex silicates

into simpler ones, with release of water⁴. In all these reactions, the observed orientations imply that the network of oxygen ions remains more or less intact throughout the course of the chemical reaction.

The most studied category of topotactic reaction has been the oxidation of metals. The nature of both the topotaxy of a thin oxide layer and the oxidation kinetics depends not only on the oxidation conditions but also on the orientation of the metal surface (see refs 5 and 6 for review).

Revcolevschi and his collaborators at the University of Paris-Sud have for some time studied the orientation relationships between the phases of lamellar eutectic structures consisting of two metallic oxides (complementing the substantial body of information on such relationships as regards metallic eutectics⁵). For their new experiments, Revcolevschi and Dhalenne³ have directionally solidified a eutectic of NiO and calcia-stabilized cubic ZrO₂ producing what is essentially an interpenetrating pair of epitaxially related single crystals which they then treat with a CO/CO₂ mixture that reduces the NiO to nickel without affecting the ZrO₂. The nickel proved to be in parallel orientation to the NiO which preceded it; the ZrO₂ phase acted as crystallographic reference. Just as earlier topotactic experiments indicated that the oxygen skeleton was maintained and unchanged, so the new experiment³ indicates that the nickel-ion skeleton remains fixed.

This pioneering experiment opens the way to various topotactic studies. One might try to mimic Gwathmey's celebrated experiment on the oxidation of a spherical copper monocrystal (showing the sharp anisotropy of oxidation rates and topotaxy) by reducing an oxide sphere, or to study the orientation dependence of reduction kinetics. It is known that the reduction rate of wuestite is sensitive to the population of point defects — it would be interesting to see whether orientation relationships are affected by defects.

Revcolevschi and Dhalenne's observations have a potential practical interest: by reducing NiO without altering ZrO₂, it is possible to make a lamellar product where adjacent lamellae are electronically and ionically conducting. Such a structure can perhaps be applied in photoelectrolysis and novel solid-state batteries. □

Plant ecology

Fertile arguments in the desert

from Jonathan Silvertown

ECOLOGISTS have been arguing recently about whether interspecific competition is responsible for observed patterns of animal distribution and abundance^{1,2}. Whereas interspecific competition once seemed to be the only process of interest to the theoretically minded, now dispersal, predation, mutualism and biogeographic history are also being considered (see ref. 1). Strangely, the recent debate has occurred almost exclusively among animal ecologists but similar arguments among plant ecologists now seem to be approaching the same conclusion.

Plant ecologists studying species distri-

Larrea bushes in the Chihuahua desert.

bution in deserts have investigated the cause of the regular spatial patterns of distribution often found in the southwestern deserts of North America and elsewhere. The commonest shrub in the Chihuahua, Sonora and Mojave deserts is the creosote bush *Larrea tridentata*, which is a conspicuous part of the sparse vegetation. Bushes, or clumps of bushes, commonly have large areas of bare ground between them and often appear regularly spaced. F. W. Went suggested that this regular spacing is the result of allelopathic (toxic) interactions between bushes³. Since then, in one of the first quantitative analyses of the dispersion pattern of *Larrea*, S. R. J. Woodell *et al.*⁴ showed that *Larrea* bushes are indeed regularly spaced at sites of low rainfall but are aggregated at sites of high rainfall. In an alternative hypothesis they suggested that the regularity is the result of competition for water between roots of adjacent bushes, with reduced competition at sites of high rainfall allowing aggregation.

M. G. Barbour^{5,6} found that regular patterns of *Larrea* were in fact quite rare. D. J. Anderson⁷ further questioned Woodell *et al.*'s claim that plants in lower rainfall areas compete for water, because bushes at these sites are at such low density that each plant actually has more available soil water than in high rainfall areas where bushes are more crowded. T. J. King and Woodell⁸ replied that the quantity of water available to bushes cannot be calculated simply from density and rainfall measurements because plant size,

surface-water runoff and infiltration of water into the ground also has to be considered. They also suggested that periods of severe drought in the past might at some sites be responsible for present-day distributions. Thus, in defending the competition hypothesis, they acknowledge the importance of other factors in structuring *Larrea* communities, as animal ecologists have had to do in defence of similar arguments about interspecific patterns⁹.

The parallel with the debate among animal ecologists can be taken further. Reassessment of competition in animal ecology has been stimulated by the use of 'null models'¹² that predict how community structure would appear in the absence of competitive interactions between species. T. A. Ebert and G. S. McMaster¹⁰ have used this approach to challenge the regularity of spacing patterns in *Larrea*, which they believe may be no more than an artefact of sampling methods, by which plants that grow very near one another are recorded as a single individual. They show that this can cause a random pattern to appear erroneously as a regular one. King and Woodell¹¹ dispute this claim, but do not explain how the competition hypothesis accounts for regular spaced clumps.

A general conclusion from the use of null models in animal ecology has been that patterns can only provide correlative evidence of the processes that structure communities. Experiments are needed to test hypotheses generated by analysis of pattern distribution. Several relevant experiments have now been performed with desert shrubs. In the field, removing neighbours of individuals of both *Larrea*

and another desert shrub, *Ambrosia dumosa*, affects the physiological water status of other plants^{12,13}. Even though this is evidence of competition for water, some of the experimental populations were aggregated. Clearly, competition does not lead inevitably to regular spacing.

We can say more than this. The desert perennial *Eriogonum inflatum* with competitors nearby is more likely to die than those plants with more distant neighbours, yet this does not change the degree of aggregation in the population. The most elaborate recent experiment¹⁵ shows how uncertain the role of root competition in producing regular spacing has become. Despite a fall in shrub density, W. H. Schlesinger and C. S. Jones found no change in the dispersion pattern of *Larrea* and *Ambrosia* at a Mojave site that has been deprived of surface water runoff by a drainage system for 45 years.

Ironically, the unknown causes of regular spacing in desert plant communities may bear some relationship to the way in which animal and plant ecologists have ignored each other. Few have considered, for example, that these plant patterns could result from the activities of seed-gathering rodents¹⁶ which forage and remove seeds between bushes and which are ubiquitous in these deserts. □

Excitation-contraction coupling

The messenger across the gap

from Andrew P. Somlyo

EXCITATION of the surface membrane of muscle results in release of calcium that is stored in an intracellular membrane system, the sarcoplasmic reticulum (SR); the Ca^{2+} released into the cytoplasm, acting through regulatory sites on Ca-binding proteins, initiates contraction. The signal from the membrane is communicated to the SR at specialized regions (triads, diads or surface couplings) where the cytoplasmic leaflets of the SR are connected to the surface membranes by quasi-periodic bridging structures across a 12–20 nm gap (refs 1,2; see figure). A major unresolved problem is the mechanism by which depolarization (or some other change in the surface membrane) is communicated

across this gap, to increase Ca^{2+} release from the SR lumen into the cytoplasm. Hypotheses to answer this question have been proposed and some, like Peter Pan, retain their youth with sustenance from the Never Land. Will the suggestion that inositol triphosphate is the messenger across the gap, as put forward for skeletal muscle on page 347 of this issue³, stay forever young?

Three main classes of mechanisms have been suggested for excitation-contraction (EC) coupling: first, direct spread of ionic current from the extracellular space through the bridging structures into the SR⁴; second, mechanical transduction via a mobile protein between the two mem-

brane systems, initiated by voltage-dependent movement of fixed electric charges in the surface membrane³; and finally, chemical transmission by a diffusible second messenger. The absence of an ionic current between the extracellular space and the SR together with the fact that Ca^{2+} release is not electrically silent⁶ have excluded the first mechanism^{4,6}, and no experimental test of the second hypothesis has yet been performed. Meanwhile, as the idea of EC coupling by chemical transmission is becoming increasingly attractive, much recent evidence suggests that inositol 1,4,5-trisphosphate (InsP_3) is the second messenger⁷ in many cells. In non-muscle cells, InsP_3 is released by the transmitter-initiated hydrolysis of polyphosphatidyl inositol in the surface membrane and it is thought to mediate transmitter-induced calcium release from the endoplasmic reticulum, a structure that is homologous with SR in muscle. The inevitable question is whether InsP_3 is also the messenger in EC coupling.

When considering EC coupling, it is important to remember that there is an additional mechanism involved in smooth muscle. Whereas in both smooth muscle and striated (skeletal and cardiac) muscle contraction is triggered by electrical depolarization of the surface membrane and its invaginations (the T-tubules) and usually by an action potential, in smooth muscle, neurotransmitters also stimulate contraction or cause relaxation through a 'pharmacomechanical coupling' independent of changes in membrane potential.

Until the discovery of InsP_3 , the most popular candidate as the messenger in EC coupling was Ca^{2+} itself. According to this theory the rapid influx of small quantities of calcium current carried by the action potential triggers the 'calcium-induced calcium release' from the SR, which provides the larger quantity of Ca^{2+} required for initiating contraction. The strongest evidence for calcium-induced calcium release⁸ is in cardiac muscle, much of it from the elegant studies of Fabiato⁹. In skeletal and smooth muscle, however, Ca^{2+} can be released from the SR even in the absence of extracellular Ca^{2+} (and, therefore, Ca^{2+} -influx); nevertheless it is still possible to argue that trigger calcium is released from a protected region, perhaps the cytoplasmic leaflet of the plasma membrane^{4,10}.

The new experiments³ show that in rabbit skeletal muscle, InsP_3 satisfies the first requirement of an EC coupling messenger — it can release Ca^{2+} from the SR. This is demonstrated both with measurements on isolated SR vesicles and by the contractile response of skinned (membrane-free) muscle fibres to InsP_3 . However, such contractions are small, slow and somewhat variable, and seem to require abnormally low free Mg^{2+} concentrations to prevent the rapid breakdown of InsP_3 . None of these objections, as Volpe *et al.* and

Electron micrographs of a triad in striated muscle (a) and surface coupling in smooth muscle (b, c); c has been freeze-etched and rotary shadowed to give a clear view of the junctional gap between the sarcoplasmic reticulum and surface membranes. T, T-tubule, an invagination of the extracellular space in striated muscle; TC SR, terminal cisterna of the sarcoplasmic reticulum; SM, surface membrane of smooth muscle (a from ref. 2; b, c, from ref. 19).

others taking a similar approach¹¹ would argue, are insurmountable. For example, in live muscle, InsP_3 may be released into the diffusionally-restricted junctional space between the SR and surface membranes (see figure); this could cause a rapid and large rise in the local concentration of InsP_3 near the terminal cisternae of the SR where Ca^{2+} is thought to be released. Such regions could even contain lower concentrations of free Mg^{2+} and of the (Mg^{2+} -dependent) phosphatases that break down InsP_3 . If the electron-lucent core of the bridging structures is a lipid, as has been suggested², it could contain InsP_3 precursors. But, for now at least, these are *ad hoc* explanations of the failures of experiments to support the hypothesis.

A more devastating blow to the role of InsP_3 as a physiological messenger of electromechanical coupling in skeletal muscle would be if depolarization were found to increase only the turnover of (mono)phosphatidyl inositol, and not that of the polyphosphatidyl inositol precursor of InsP_3 , and/or if an increase in InsP_3 were shown to be a slow side-effect of acetylcholine released by nerves, and did not precede twitch contraction. The increased phosphatidyl inositol turnover evoked in frog skeletal muscle by depolarization with potassium is far more prolonged than

the duration of Ca^{2+} -release¹², and InsP_3 seems to cause only very modest calcium release from isolated cardiac SR¹³.

The most compelling evidence for a physiological role of InsP_3 in muscle is neither in electromechanical coupling nor in striated muscle, but as a transmitter of pharmacomechanical coupling in smooth muscle. In these tissues various physiological transmitters (cholinergic, adrenergic and peptides) can stimulate the breakdown of polyphosphatidyl inositol to produce InsP_3 (refs 14–16). It is important to note that depolarization does not stimulate breakdown of polyphosphatidyl inositol in smooth muscle^{14,15}, whereas cholinergic agents can stimulate such breakdown during pharmacomechanical coupling¹⁵. The release of calcium from smooth muscle cells by InsP_3 has been demonstrated in two laboratories using different methods^{17,18}. Furthermore, low micromolar concentrations of InsP_3 can cause sustained, graded contractions of smooth muscle even in the presence of the highest free Mg^{2+} (1–2 mM) likely to be present *in vivo*¹⁸. Therefore, it is probable that InsP_3 mediates at least the part of pharmacomechanical coupling that is caused by a voltage-independent release of Ca^{2+} from the SR, and seems to be similar to Ca^{2+} release from the endoplasmic reticulum of non-muscle cells.

It remains to be determined whether the effects of InsP_3 on the SR of skeletal muscle will turn out to be a major physiological mechanism or simply an interesting laboratory phenomenon like the effects of fatty acids and adenine nucleotides, which can release Ca^{2+} or potentiate Ca^{2+} -induced Ca^{2+} -release. The new findings will, at the least, stimulate the hunt for an identifiable messenger of EC coupling. In the background, like the crocodile following Captain Hook, the spectre of a more physiologically active inositol phosphate lurking in InsP_3 preparations haunts investigators in this exploding field. □

Laser physics

Advances in free-electron lasers

from M.W. Poole

FREE-electron laser (FEL) research is continuing to break new ground; experimental configurations already exist and further modifications are being planned. The potential rewards for the successful development of such a coherent radiation source are very great, whether for radar and telecommunications, fusion energy research, photochemical processing (such as isotope separation) or fundamental research in topics such as non-linear spectroscopy. Ambitious plans are being laid for a 500-Å device and this technology is probably at least as promising as any other for the ultimate goal of an X-ray laser.

The recent announcement that yet another group has joined the increasing band of successful FEL experimenters has significance beyond its initial results. The massive resources of the Lawrence Livermore National Laboratory in California, aided by scientists from Berkeley, have now been brought to bear on the development of this exciting new technology. It seems inevitable that they and their major rivals at the Los Alamos National Laboratory could dominate future progress. Their latest results have demonstrated both exceptionally high gain ($\sim 3,000$) and attractive energy-transfer efficiency (~ 5 per cent) for millimetre waves and the race is now on to extend this to shorter wavelengths.

So far there have been two very distinct FEL communities: those using electron accelerators with beam-current densities sufficiently low that energy transfer is dominated by a single-particle (Compton) interaction, and those with access to intense beams where collective (or Raman) effects become important. The former groups have led the way since the first FEL demonstration by John Madey's team at Stanford University in 1976; important developments were summarized last year in these columns (Pidgeon, C.R. *Nature News and Views* 308, 772; 1984) which noted that four oscillators had operated over the range 0.6–10.6 μm , and since then a fifth device has extended this to 400 μm at the University of California, Santa Barbara. In fact the intense-beam workers could claim a better pedigree that extends back to the ubitron — an early centimetre wave device — and the cyclotron maser that was the centre of attention at the Naval Research Laboratory (NRL) in Washington at the time of the Madey experiments. It was the chance detection of submillimetre output from a cyclotron maser, caused by interaction of the electron beam with its 20-mm generated radiation reflected off a window, that first initiated a long programme of FEL work at

NRL over the past decade, culminating in the reporting of huge gains (120 dB m^{-1}) at 35 GHz (Gold, S.H. *et al. Phys. Rev. Lett.* 52, 1218; 1984). However, all intense-beam FEL experiments until recently have found it necessary to use an additional solenoidal field to focus the large electron beams along the length of the interaction region; such a field can contribute strong cyclotron emission that has led to ambiguities in the interpretation of the output from these devices.

What the Livermore/Berkeley collaboration has been able to announce (Orzechowski, T.J. *et al. Phys. Rev. Lett.* 54, 889; 1985) is a 35 GHz amplifier with high gain and efficiency that exhibits remarkably good agreement with theoretical expectations over a very wide range of signal levels. The experiment was started with the aim of extending collective FEL outputs down to wavelengths similar to those of the Compton devices; this would, for example, allow immediate application of the FEL to plasma heating of fusion mirror machines. Since then, President Reagan's Strategic Defence Initiative has injected financial adrenalin into FEL activities and high power at visible wavelengths is now the declared objective.

The new amplifier, ELF (electron laser facility), is based on the Livermore experimental test accelerator, a linear induction device that can deliver beams of up to 10 kA at 4.5 MeV, although only for short pulses of 30 ns at about 1 Hz. In fact the experiments have been carried out at slightly lower energy and with the electron current heavily collimated to about 500 Å to reduce the beam cross-section in the interaction region. A 3-m-long pulsed electromagnet of 98-mm periodicity induces the required energy transfer between the electrons and an accompanying wave supported by a thin stainless steel waveguide. Additional quadrupoles assist the electron beam focusing but there is no axial field.

First, the team explored the 'super-radiant mode' (laser terminology for amplification from an initial noise signal, in this case the spontaneous synchrotron radiation emitted by a relativistic electron in any magnetic field) and achieved an amplification of 13.4 dB m^{-1} down the periodic magnet. Next, a 60-kW pulse from a magnetron was injected into the interaction region and emerged as a very impressive 80 MW peak output power. In fact the FEL goes into saturation after about 2.2 m and thereafter its power oscillates along the length of the interaction.

A crucial feature of the Livermore approach has been to develop theoretical models in parallel with the experiment-

ation; this has involved extensive computer simulations to include such three-dimensional behaviour as the off-axis electron trajectories and the transverse electromagnetic mode characteristics. Their reward has been an encouraging agreement of predicted and observed FEL behaviour that sets a standard for others to emulate. In the near future the group intends to investigate enhanced efficiency to push the saturated power to still higher levels. At present the efficiency limit is set by the loss of energy from the electron beam detuning the resonant interaction between the charged particles and the wave. To overcome this the Livermore periodic magnet has 15 separate power supplies that can progressively lower the field strength along the interaction region to match the reducing electron energy, thus maintaining the resonance condition. Eventually, Livermore hopes to switch the experiment to an even more powerful induction linac, the advanced test accelerator; this might then permit the same extraordinary performance to be achieved in the infrared region.

Meanwhile, the single-particle FEL community has not been idle. A revolutionary new oscillator in the far infrared has been produced by Elias, one of Madey's original team at Santa Barbara. This takes a giant step towards extremely high average power FEL operation, because the accelerator is a 3 MV Van de Graaff facility that can in principle provide continuous wave electron beams rather than the low-duty cycles typical of most other accelerators. To achieve this would require almost all of the electron beam to be recovered after passing through the FEL, returning it to the high-voltage terminal by a suitable deceleration and collection process; this group has already demonstrated that this can be done. A laser with multikilowatt average power output cannot be far away.

The United Kingdom Heriot Watt-Glasgow-Daresbury collaborative FEL project is now fully assembled at the Kelvin Laboratory, East Kilbride. Spontaneous emission has been detected at both infrared and visible wavelengths, the latter making use of higher harmonic emission generated in the powerful periodic magnet system. Laser oscillation above threshold at 10.6 μm is now being attempted and it is also hoped to demonstrate a wide tuning range. Subsequently to this it is intended to study FEL action on a higher harmonic, a topic of great current interest as it promises to extend FEL operation down to wavelengths previously considered unattainable on such medium-energy (10–100 MeV) accelerators. Apart from this project, sadly almost all funded FEL research is now concentrated in the United States. □

M.W. Poole is in the Synchrotron Radiation Division, SERC Daresbury Laboratory, Warrington WA4 4AD, UK.

Pesticides and the decline of Guam's native birds

SIR—Diamond¹ recently reviewed the factors which might be responsible for the decline of Guam's native birds. Although Diamond's commentary was based on a report by Jenkins² that included several hypotheses (pesticides, introduced predators and disease), Diamond suggested that pesticides were the most likely cause.

The pesticide hypothesis evolved from two reports. In 1946, Baker³ stated the organochlorine pesticide DDT was used extensively on the island during and after the Second World War. In 1977, Draho⁴ reported concentrations of DDE, a metabolite of DDT, of less than 0.4 p.p.m. in the carcass lipid (about 0.03 p.p.m. whole carcass wet weight) or swiftlets (*Aerodramus vanikorensis bartschi*) and concentrations of DDT and DDE of less than 0.10 p.p.m. (believed to be on a dry weight basis) in swiftlet guano.

Diamond¹ and others^{2,4} considered these data indicative of potential harmful effects of DDT, a conclusion not supported by critical evaluation of Draho's data or concentrations of DDT and DDE (≤ 0.2 p.p.m. dry weight) detected in swiftlet guano I collected in 1981. The carcass residues reported by Draho⁴ indicate that swiftlets were exposed to DDT or DDE, but concentrations are a fraction of those associated with mortality (> 600 p.p.m. in carcass lipid)⁵ or reproductive failure (78 p.p.m. whole carcass wet weight)⁶ in birds. Residues in the guano are difficult to interpret because relationships between concentrations of organochlorines in bird faeces and those in their carcasses have not been determined. These relationships have been determined for bats, however, and residues in swiftlet guano are similar to those in guano of bats (*Myotis grisescens*) whose carcasses contained only a fraction of lethal levels⁷.

Soil and avian prey I collected in 1981 were essentially free of organochlorine pesticides; only a sample of skinks (*Carlia fusca*) contained a detectable concentration (DDE at 0.04 p.p.m. wet weight, 0.13 p.p.m. dry weight). Residues in shrews (*Suncus murinus*) trapped in 1981 did not exceed 0.30 p.p.m. wet weight. These levels are also less than those known to adversely affect birds or small animals.

In addition, it is unlikely that present use of pesticides by civilians or the military on Guam is responsible for the decline. Agricultural lands comprise less than 1% of the island's total area and more than 84% of the pesticide used is organophosphates or carbamates⁸, chemicals that do not persist in the environment⁹. Of the four pesticides used the most (malathion $>$ diazinon $>$ naled $>$ carbaryl), only diazinon has been implicated in wildlife mortality elsewhere⁹. Malathion is also the pesticide used in the greatest quantity by the military, and with few exceptions,

use has been restricted to housing areas. Although spray operations by the military may have temporarily decreased insect abundance, such decreases cannot explain the continuing decline of the island's avifauna.

It is unfortunate that Diamond¹ and others^{2,4} incorrectly equated pesticide use or residues on the island with harmful effects. Although the use of some pesticides can be hazardous to birds, and effects associated with the use of DDT still persist today^{9,10}, there are no data supporting the hypothesis that pesticides are responsible for the continuing decline of Guam's native avifauna.

SIR—In his *News and Views* piece on the "Possible effect of unrestricted pesticide use on tropical birds"¹, Diamond used Guam's avifauna as an example based on Jenkins' report *The Native Forest Birds of Guam*². Jenkins suggested that pesticide usage may be responsible for the drastic decline of Guam's birds. However, due to publication time lag, Jenkins' monograph is only current through 1979. Research since that time suggests that although pesticides were extensively used on Guam, they do not appear to be responsible for the general decline of the avifauna (C. Grue, personal communication). However, pesticides may have impacted certain species in the past, such as the insectivorous Vanikoro swiftlet and sheath-tailed bat.

My research has focused on the possible roles of introduced avian diseases and predators. Between 1982 and 1984, a variety of birds were sampled in collaboration with the USFWS National Wildlife Health Laboratory for parasites, bacteria and viruses and two sentinel experiments were conducted. To date, no infectious organisms have been isolated that could account for the current extinctions and range reductions.

Feral dogs, cats and rats are a problem on all major islands in the Marianas. The only predator unique to Guam is the brown tree snake, *Boiga irregularis*. The snake is the major cause of the decline of

the forest avifauna. This species was introduced to Guam in 1946, and its range expansion corresponds to the avian range contraction. Predation intensity on bird-baited traps is extremely high, and alternative prey items have also declined. Supporting data are currently being prepared for publication.

Thus, although Guam may not be the best example for the dangers of unrestricted pesticide usage, it certainly should serve as a warning of the potential disastrous effects of introducing exotics to island ecosystems.

Electrostatics revindicated . . . classically . . .

SIR—Berezin¹ has considered the minimum energy configuration of N point charges placed inside or on a circle. This problem has a well defined continuum limit, namely the distribution of charge over a metallic disk. The solution, given in Jeans' textbook², has a finite charge density all over the disk rising to infinity at the edge. Consistency with this limit demands that for increasing N , charges (in the minimum energy state) leave the edge and occupy the interior. The use of a $1/r$ rather than an $\ln r$ potential implies that the circle is really a disk embedded in three-dimensional space and there is thus no contribution with the usual notion that charges reside on the surface of a conductor. These arguments imply that in the case of a sphere, there will be no minimum energy solution with charges in the interior, as is already clear from Earnshaw's theorem³.

. . . by conducting ellipsoid

SIR—A very old problem in electrostatics is to find the distribution of charge on a conducting ellipsoid which will be taken to be an ellipsoid of revolution. The charge density is of course confined to the surface and is everywhere finite. If we let the length of the axis of rotation go to zero we get a highly idealized two-dimensional object, a two-dimensional (infinitely thin) conducting disk. If the radius of this disk is R , the charge density is well known to be proportional to $(R^2 - r^2)^{-1/2}$. This density

must be a fairly good approximation to the distribution of a number of identical charges (say electrons) placed on the disk. It is not confined to the circumference and it is *not* zero at the centre. Hence there is really nothing unexpected in the results given by Berezin¹ who shows that 12 identical charges distributed evenly on a circle have a greater potential energy than 11 charges on the circle and one at the centre. Perhaps the fact that 12 is the precise number at which one charge is "expelled to the centre" is mildly surprising.

Berezin goes on to conjecture that a similar "spontaneous ejection" of charge to the centre will occur in three dimensions and that this "may lead to some modification of usual theorems of electrostatic stability which claim that at the state of equilibrium all charges . . . are always located at the surface." I think that this conjecture is wrong, and is a nice example of incorrect generalization from two to three dimensions. For example, arguing from two² to three dimensions about the propagation of an impulsive wave emitted from the origin would lead one to the false conclusion that there is a residual disturbance left at the centre in the three-dimensional case.

However, Berezin's letter raises a question to which I have been seeking an answer for some time. It seems clear that it is possible to place an arbitrary number, N , of electrons on a conducting sphere. The question is how do they arrange themselves?

There is little doubt in my mind that they will arrange themselves on the surface, and intuitively the answer would seem to be given by simple symmetry arguments when $N=1, 2, 3, 5$ and $4, 6, 8, 10, 20$, where the second set of numbers are the numbers of vertices of the five regular polyhedra in three dimensions. However, as Berezin has pointed out (in personal communication), such arguments are false in the case where $N=8$. Having the electrons at the vertices of a regular cube has a *higher* energy than when one face is rotated relative to the opposite face by 45° , the distance between the faces being held constant. A quantum treatment of this problem would also be interesting and could also yield mean values of the multipole moments of the system.

. . . with charged polygons

SIR—The classical electrostatic energy of N point charges, q , symmetrically disposed on a circular circumference with radius R has been recently discussed here (A. A. Berezin, *Nature* **315**, 104; 1985). A surprising feature of these regular poly-

gonal systems was reported for $12 \leq N \leq 400$. Such arrangements are energetically unstable with respect to displacement of one charge to the centre and regular circumferential redistribution of the remaining $(N-1)$ charges. On this basis Berezin made two conjectures: (1) that such a rearrangement is energetically favourable for any large N and (2) that his large- N result indicates a violation of the familiar electrostatic theorem. For a conducting body at electrostatic equilibrium, any net charge must be located at the surface (Faraday shielding).

It should be pointed out that conjecture (2) cannot follow from the large- N polygon results.

If these systems are to model a classical conducting system, their electrostatic potential energy should vary as: $W = \frac{1}{2} cq^2 N(N-1)$ with c a geometrically determined constant (capacitance coefficient). This in turn requires that the electrostatic potential at any vertex location due to the other $(N-1)$ charges should be $U = cq(N-1)$. Evaluation of exact electrostatic potentials for polygons with $N=10^3, 10^4, 10^5$ yields respectively $U=2,238.7970; 29,717.3261$ and $370,466.8178$ (units of q/R).

Clearly the required linear N dependence does not occur. This failure relates to the usual logarithmic distance dependence of electrostatic potentials near linear charge distributions. Thus the polygonal charge arrangements cannot model a conducting system.

For the problem at hand, the potential U may be approximated by exactly summing the contributions of the $2j$ charges closest to a vertex location and treating the remaining charges continuously. For example, choosing $j=18$ and N large:

$$U \approx \frac{Nq}{R} \left[1.112527455 + \frac{1}{\pi} \ln \cot \frac{37\pi}{4N} \right]$$

This expression reproduces the potential energy, U , for polygons with $N \geq 10^3$ with fractional accuracy better than 2.3×10^{-5} ; this accuracy improves with increasing N . The non-linear N dependence is manifest. Using such an algebraic approximation Berezin's first conjecture, the instability of any large- N polygon system, is readily confirmed.

For N surface charges regularly distributed on the surface of a sphere with radius R , the limiting form of the electrostatic energy is:

$$W = \frac{1}{2} \frac{q^2}{R} (N) (N-1)$$

Accordingly for the spherical surface, expulsion of one charge to the centre is energetically possible only in the infinite N limit.

. . . but for 12 equal point charges?

SIR—Berezin has recently shown that the minimum energy configuration for N equal point charges placed in a circle is different depending on whether N is less than, greater than or equal to 12 (*Nature* **315**, 104; 1985). In the former case ($N < 12$) the configuration of minimum energy is with the N charges at the vertices of a regular polygon inscribed in the circle (configuration A); in the latter case ($N \geq 12$) a lower energy configuration is obtained with one charge expelled to the centre of the circle and $(N-1)$ charges at the vertices of an $(N-1)$ sided inscribed polygon (configuration B). Berezin verified this result up to $N=400$ and claimed it was "very likely" true for all $N \geq 12$. It is easy to show the result does indeed hold for all $N \geq 12$ as follows.

The energy of N charges arranged in configuration A is

$$W_A(N) = \frac{N}{2} \left\{ \sum_{i=1}^{(N-1)/2} \frac{1}{\sin \pi i/N} + 0.5 (N \text{ even}) \right\} \quad (1)$$

and arranged in configuration B is

$$W_B(N) = \frac{(N-1)}{2} \left\{ \sum_{i=1}^{(N-2)/2} \frac{1}{\sin \pi i/(N-1)} + 2 + 0.5 (N \text{ odd}) \right\} \quad (2)$$

It follows simply from equations (1) and (2) that

$$W_B(N) = W_A(N-1) + (N-1) \quad (3)$$

Hence the condition that configuration B gives higher energy than configuration A ($W_B(N) > W_A(N)$) is true for those N where

$$W_A(N) - W_A(N-1) < (N-1) \quad (4)$$

By inspecting the numerical data for $W_A(N)$ only, looking say at the range $2 < N < 40$, it is possible to see that the inequality (4) is satisfied for $N < 12$ as shown by Berezin. It is also easy to see that the left hand side of inequality (4) is increasing faster than $(N-1)$ as N runs beyond 12. Hence the result found by Berezin is true for all $N \geq 12$.

ANNOUNCING AN IMPORTANT NEW JOURNAL

ADVANCED DRUG DELIVERY REVIEWS

1st issue available April 1986

Aims and Scope

The journal will publish comprehensive review articles describing current and emerging aspects of research on the design and development of advanced drug delivery systems and their application in critical experimental and clinical therapeutics.

Articles will review the current status of a specific topic, giving equal emphasis to the identification of the major problems that must be solved to allow further successful development, evaluation of shortcomings in current conceptual and technical approaches and discussion of possible solutions to these difficulties.

The scope of the journal will be broad and will not focus exclusively

on particular delivery systems or target diseases. The primary aim is to create an authoritative forum for the critical analysis of research efforts across the entire spectrum of current investigations in advanced drug delivery systems and their application in human and veterinary medicine and in agriculture.

Editors-in-Chief

G. POSTE, *Smith Kline and French Laboratories Philadelphia, PA, U.S.A.*

E. TOMLINSON, *Ciba-Geigy Pharmaceuticals, Horsham, West Sussex, U.K.*

Those wishing to submit an article should contact one of the editors for details.

Subscription Information

1986 volume 1 (1 volume in 3 issues).

Price: US \$120.75 / Dfl. 374.00 including postage and handling.

Single issues are also available upon request.

PLANT SCIENCE

an international journal of
experimental plant biology

(Formerly Plant Science Letters)

Plant Science will publish, in the minimum time, papers recommended by its referees in all areas of experimental plant biology. Papers describing experimental work with multicellular plants and plant-like microorganisms (protists, including algae and fungi and blue-green algae (cyanobacterial)) are appropriate.

Submission of manuscripts in the broad areas of biochemistry (including enzymology), bioenergetics, cell biology, development, genetics, molecular biology, physiology and structure in relation to function as well as fundamental work in these areas related to agriculture and phytopathology is invited. The following examples of areas covered by Plant Science are not exhaustive, original work of high quality in any area of experimental plant biology, broadly construed, will be welcome.

Example of areas covered by PLANT SCIENCE:

- Cell and Tissue Culture, protoplasts, cell fusion
- Cell organelles including development of plastids and mitochondria, cell walls
- Cellular and Molecular Genetics
- Enzymology and Intermediary Metabolism
- Inorganic Metabolism including nitrate reduction, nitrogen fixation, sulfur metabolism, other macro and macro elements
- Molecular biology of plant cells
- Nucleic acids, proteins, and their metabolism
- Nucleocytoplasmic interactions
- Photosynthesis, respiration and carbon metabolism
- Phytochemistry and secondary plant products
- Pigments, including Biochemistry, Metabolism and Biosynthesis of Chlorophylls, Anthocyanins, etc.

- Regulation of growth, development and differentiation
- Ultrastructure and cellular fractionation
- Viruses
- Water relations, transport of solutes etc.

PLANT SCIENCE now has a larger format and comprises the following sections:

- Physiology and Biochemistry
- Molecular Biology
- Cell and Tissue Studies *In Vitro*
- General

The rise of 'Mobilism'

Roy Porter

The Dark Side of the Earth. The Battle for the Earth Sciences: 1800-1980.

By Robert Muir Wood

George Allen & Unwin: 1985. Pp.246. £11.95, \$19.95.

"GEOLOGY is dead; long live the Earth sciences". This in a nutshell is the message of Robert Muir Wood's analysis of continental drift from Wegener's chequered career up to the sudden and stunning success of "mobilism" in the plate tectonics revolution of the 1960s.

At one level, this bold survey can be read with equal pleasure and profit as one of the best interpretations of that astonishing scientific upheaval. Unlike Anthony Hallam's *A Revolution in the Earth Sciences* (Oxford University Press, 1973) it does not primarily aim to evaluate the inner logic of successive geological theories; nor does it rival the dramatic blow-by-blow commentary on tectonic breakthroughs offered by William Glen's *The Road to Jaramillo* (Stamford University Press, 1982). But Dr Wood's reading has special virtues of its own. He offers the best account yet of the nineteenth century heritage of speculations about oceans and continents which formed the matrix of drift theory. And he is adroit in bringing his protagonists to life and illuminating their particular parts in the story. Harry Hess is identified as the senior figure who consistently championed younger researchers such as Fred Vine in their heterodox investigations; John Tuzo Wilson is shown to have been the right man in the right place at the right time for propounding the wider "mobilist" synthesis. And due weight is given to the crucial role played by Teddy Bullard as a catalyst, above all in making Anglo-American co-operation in this enterprise so fruitful. Not least, Dr Wood commands a good turn of phrase, and patiently weaves together with enviable skill all the strands of a highly complex narrative.

So here is a sure-footed and wide-ranging account of the triumph of continental drift, with much to offer to specialists and non-specialists alike. But Dr Wood has bigger fish to fry. His case is that the plate tectonics revolution was not just a great transformation in geology — indeed, it is wrongly interpreted if we see it as a revolution in geology. For it was rather a revolution *against* geology.

From its early nineteenth century giants up towards the present, geology's great triumph lay in the stratigraphical and palaeontological vision, in generating the science of the rocks, indeed, a love of the rocks. Geology studied the land masses, especially their mountains. As synthesized in classics such as Eduard Suess's *Das Antlitz der Erde* (1885-1909), it theorized the continents in the context of a

stable, if shrinking, Earth, and then minutely studied their deformations through tireless fieldwork and mapping.

The plate tectonics revolution has left this either wrong or stranded high and dry as an irrelevance. The "mobilist" vision swung attention away from the establishment's preoccupation with hammering out ever more data about the strata. Instead "drifters" turned the whole Earth into their parish and their problem. Unlike conventional geologists, they followed Lyell's advice (think like intelligent amphibians) and gave the ocean beds at least as much attention as the land masses. They insisted on tackling questions, such as the global distribution of the continents, from which orthodox geology shied away; they deployed specialist skills in fields such as seismology and geomagnetics not routinely possessed by pukka geologists; and they ended up proposing a theory which could not be judged — for or against — at the bar of conventional geology.

In other words, the revolution in plate tectonics was the overtaking of geology by an alliance of disciplines which we may call geophysics. Or, put another way, enter the Earth sciences, marching under the banner of a global theory, which rendered old geology obsolescent in much the same way as Darwin's evolutionism left behind classificatory natural history as a key to the economy of life.

This was a revolution made by aliens. Some were geographical outsiders, such as the South African, Alexander Du Toit, or Warren Carey from Australia. Others were disciplinary marginal men, classically of course Wegener himself (first and foremost a meteorologist, as Dr Wood rightly insists, while perhaps unduly playing down his geological credentials). Practically all the pioneers of "mobilism" had training or research experience in some branch of geophysics — often in seismology or geomagnetism — which set them apart from true-blue geologists. Not least, "mobilism" was typically the brainchild of the "mobile", the young and ambitious, and was perceived by the old guard to be unsettling (in America it was dubbed "leftist", in Russia, "bourgeois").

Thus the plate tectonics revolution did not emerge out of the geological main stream. Above all, its inspiration came from that late arrival, deep-sea geology. And this in itself would have been unthinkable without the gigantic sea-bed surveying operations funded at huge expense by allied governments during and

after the Second World War (projects in which Hess, Ewing and Bullard were all prominent); and then, at a later stage, without the United States pouring money into seismology to monitor nuclear tests. Thus strategic needs produced new fields of expertise; these led to the discovery of the magnetic field anomalies of seafloor rocks, which in turn proved the surprising youth of the ocean floor, and gave rise to the key idea of seafloor spreading, that *since qua non* of the vision of continents borne on mobile plates.

Of course, Dr Wood is not arguing that conventional geology contributed nothing at all to this. But the fact that even so catholic and prescient a geologist as Arthur Holmes got so far yet no further in convincing himself and others of drift, perfectly shows its limitations even at its best. And, at its worst, orthodox geology proved to be an ostrich.

So plate tectonics should not be seen as a revolution in geology, but as marking geology's eclipse, a refocusing of scientific attention away from the rocks towards the whole Earth, a re-think of planet Earth for the space age. Science thus advances, Dr Wood argues, not by accumulating data, nor even by internal theory switches, but by massive re-groupings of disciplines. The old gods are devoured not by their own children but by their neighbours' (except perhaps in the Soviet Union where geological gerontocrats have had more success in keeping the new "drifters" at bay). Late Victorian geology had resented being put in its place by the physico-mathematical imperialism of Lord Kelvin, and had unilaterally declared its independence of physics. Now, a century later, geophysics has had its revenge.

Occasionally, the contrast Dr Wood draws between senile geology and virile Earth science is overstated for polemical effect (his own evidence sometimes gives it the lie); and it is a pity that, drawing too freely upon hindsight, he oversimplifies certain complex figures, such as T.C. Chamberlin and Maurice Ewing, and turns them into whipping boys. Although providing attractive line drawings of the main protagonists, the book would have benefitted, I think, from some explanatory diagrams. Yet all praise to him for recognizing that in understanding the history of science no less than in understanding the history of the Earth, "fixism" will not do. No more than the continents, are the sciences themselves fixtures; they too are subject to drift, expansion and subduction. This is an important re-interpretation, whose "mobilist" vision should send some shock waves through the geological establishment. □

Roy Porter is Senior Lecturer at the Wellcome Institute for the History of Medicine, Euston Road, London NW1 2BP, UK and author of *The Making of Geology* (Cambridge University Press 1977).

Getting down to the bare bones

Richard Potts

The Analysis of Animal Bones from Archeological Sites. By Richard G. Klein and Kathryn Cruz-Uribe. University of Chicago Press: 1984. Pp.266. Hbk \$19.95, £18.95; pbk \$8.95, £8.50.

INVESTIGATION of past human activities and ecological settings requires many analytical steps and cautious weighing of the processes that transform living phenomena into buried, fossilized traces. Archaeological faunal remains—one such “end product” of this transformation—have provided extremely important, albeit controversial, evidence about early hominid behaviour and environments. After determining the species, body part, sex and age of death of the animals represented by bone specimens, zooarchaeologists often attempt to estimate the relative number of individuals or bone units of each species found in an accumulation of bones; further, they may construct mortality/age distributions for well-represented species. These and other quantitative data help to test ideas about environmental change; catastrophic versus attritional death of animals; whether humans, carnivores or geological agents were responsible for bone aggregates; and whether humans hunted or scavenged, and how they selected certain species and body parts.

The theme of this volume is the entire process by which zooarchaeologists interpret the past from the assemblages of vertebrate bones often found in

archaeological excavations. The first of two sections introduces lucidly the fundamentals of animal bone identification, faunal data collection and analysis. The second provides computer programs in BASIC that generate data used widely in faunal analysis (minimum number of individuals, age distributions and so on). These programs are explained clearly and the procedures used to quantify bone assemblage characteristics are discussed thoroughly. Inferences about ancient people, their sites and environments are illustrated largely from Klein's own research on prehistoric faunas of southern Africa and Europe. Thus, the book provides an excellent summary of the approaches Klein has developed.

In illustrating certain aspects of faunal analysis, the authors offer interpretations that appear *post hoc*, without due consideration of alternatives; this will disquiet some researchers. Others may feel that the authors' distinction between the comparative and taphonomic approaches to faunal studies is unwarranted, especially since the latter approach (which examines how modern processes create faunal patterns) is played down.

These potential points of dispute do not overshadow the book's value, however. It will be widely used as a text on fundamental aspects of faunal analysis and as a source of ideas and useful programs for generating data that help to explore the subtle, bony traces of ancient human activities and environments preserved in the geological record. □

Richard Potts is Associate Curator in the Department of Anthropology, National Museum of Natural History, Smithsonian Institution, Washington, DC 20560, USA.

The wonderful sky at night

Martin Harwit

The Cambridge Atlas of Astronomy. Edited by Jean Audouze and Guy Israël. Cambridge University Press: 1985. Pp.432. £29.95, \$75.

How wonderful to open this volume to find an absolutely lavish collection of new drawings, charts, explanatory diagrams, illustrated tables and photographs—not just of astronomical objects, but also of terrestrial fossils and atmospheric and volcanic structures.

There are charts and maps of all kinds, and pictures of the lunar surface and of all the planets and satellites visited by spacecraft. Some of these we have seen before, but most of them are selected to be instructive: tracks left on the Moon's surface by the Apollo lunar vehicle, along-

side lunar dust, highly magnified, showing an occasional spherical droplet, and next to that an electron micrograph of a single grain showing tracks of solar cosmic rays that have bombarded the lunar regolith leaving a record of solar activity over past aeons. Over the page we find a picture of a micrometeorite, followed by views of slices of larger meteorites and embedded ion tracks. Just by looking at such sequences readers will gain insight into the nature of lunar surface material, meteoritic matter and some of the processes to which both have been subjected. In turn, they will better appreciate the way a knowledge of these processes helps us to understand the past histories of the materials which make up the Solar System.

This, then, is a beautifully produced book of great pedagogic value. Amateur astronomers, high school students and professionals will find here a visual display which is both arresting and informative. What I am about to say should, therefore, not discourage one from investing in this volume.

My particular disappointment started when I stopped looking at the illustrations and began reading the text. In just the first hour of browsing I noted a dozen flaws of all kinds. There are numerous typographical errors, and the index appears to have been compiled with insufficient care over the cross-referencing, which is so important in a volume such as this. More specifically, a figure caption (p.11) describes the telescopes used by Galileo, and adds, “The principles of these telescopes were conceived in Venice by an unknown genius”. Actually, these instruments first surfaced in the Netherlands, late in 1608, roughly a year before Galileo began his observations. And on p.387 we find the statement: “The existence of neutrinos was proposed for the first time by Paul Dirac on a theoretical basis to explain the conservation of the angular momentum, or spin of the ensemble of particles produced by the beta disintegration of the neutron”. Actually it was Wolfgang Pauli, with some help from Enrico Fermi in naming the particle, who conceived of the neutrino for conserving energy in beta decay.

More serious, however, is the question of purpose. How much should the text explain—couldn't the occasional bit of calculus have been avoided through use of a simple diagram? One has the impression that the editors wanted to pack every possible concept into this single volume—massive neutrinos, the number of neutrino generations, proton decay and other current exotica. This has taken its toll on clarity. For example the section on cosmology begins by listing five principles alleged to guide the construction of cosmological models: “The principle of uniformity, the cosmological principle, the anthropic principle, the principle of equivalence and Mach's principle” (p.381). But Mach's principle still does not fit into any of our current theoretical models; and the anthropic principle merely tells us to disregard theoretical models which don't ultimately produce cosmologists. Everything seems to have been crammed in with little regard for separating the important from the frivolous.

Still, the editors and publisher have done remarkably well with the illustrations and, on balance, I recommend the *Atlas* highly. I just hope that the text can be thought through once more, in time for a well-deserved second edition. □

Martin Harwit is a Professor in the Department of Astronomy, Cornell University, Ithaca, New York 14850, USA.

The unseen revealed

A. Howie

The Beginnings of Electron Microscopy. Edited by Peter W. Hawkes. Academic: 1985. Pp.633. \$88, £67.

DURING the 1920s, the work of Busch and Gabor on the focusing action of short magnetic solenoids in the high speed cathode ray oscillograph, and the separate, celebrated discoveries in electron diffraction, sparked off an idea which some minds — with a faith reminiscent of a mediaeval cathedral-builder — took seriously. That idea was the construction

The Met-Vick EMI, the first commercially produced electron microscope. Installed at Imperial College, London in 1936.

of microscopes to surpass the resolution of optical instruments by as much as five orders of magnitude, a limit deduced purely from the electron wavelength.

Here, in partially coherent illumination from a variety of authoritative sources (delightfully illuminated themselves by Cosslett), one can learn how the idea survived the technical obstacles of power supply instability and poor vacua, as well as the deeper problem of lens aberrations. It seems that other difficulties, such as the slump of the early 1930s and the Second World War (with enemy occupation of Holland and France to be borne by Le Poole, Grivet and Dupouy), were only marginally more serious than the general indifference of optical microscopists. Did they simply exaggerate the beam damage problem? Or were they more realistic about the looming difficulties of specimen preparation and image interpretation described here by Drummond, Hall and Fernandez-Moran?

In this enjoyable collection of reminiscences, Dr Hawkes has unfortunately missed some potentially important contributions because of illness, death or prior publication elsewhere. The brilliant construction by Prebus and Hillier, two

graduate students at Toronto, during four months in 1938, of an instrument eventually achieving 100Å resolution is only briefly mentioned. Less serious is the absence of a major contribution from Ernst Ruska (whose own book, *The Early Development of Electron Lenses and Electron Microscopy*, appeared in English translation five years ago). His towering achievement is manifest here from different viewpoints. As noted by Mulvey, the transmission microscope producing today's images at atomic resolution follows in all crucial respects the original Ruska design. Restricted, however, by lens aberrations to the small-angle range where coherent scattering effects dominate, the instrument depends on a marriage of electron optics and electron diffraction far closer than anyone then envisaged. Although the reader may trace in Le Poole's account the instrumental foundations of that partnership (also laid by Boersch), sample its fruits in Dupouy's magnificent high-voltage images or sense with Hibi the holographic future, he must turn elsewhere (for example to *Fifty Years of Electron Diffraction*, published by Reidel in 1981) to appreciate the enormous benefits which the union brought to both disciplines.

As its originator von Ardenne describes, scanning electron microscopy provides a contrapuntal theme even though it shares the same origins with the more conventional transmission method. A much better understanding of electron beam scattering processes is required, however, to exploit fully the rich range of imaging modes available in scanning. Its wide application depends more on ease of specimen preparation and depth of field than simply on resolution. The post-War exploration of these questions and the development of instruments for manufacture are recounted by Oatley and his colleagues. This contribution, as well as Mulvey's, covers two of the three principal manufacturing initiatives in electron optics where, contrary to received doctrine, British industry exploited an idea originating elsewhere. Le Poole and Kanaya treat the early stages of the important Dutch and Japanese electron optical industries.

A third theme, dating from pre-War Germany but little mentioned here, is the field emission microscope. Closer to the simplicity of the Leeuwenhoek microscopes than anything else in electron optics, the field emission tip has fathered the recent spectacular advances in scanning transmission and in scanning tunnelling microscopy. Before long, perhaps, Dr Hawkes will edit a second volume rediscovering in this more recent progress our great debt to the persistent vision of the early pioneers. □

Plumbing the depths

Stephen Moorbath

Archaeo Geochemistry: The Origin and Evolution of the Archaean Continental Crust. Edited by A. Kröner, G. N. Hanson and A. M. Goodwin. Springer-Verlag: 1984. Pp.286. DM87.

UNTIL recently, the Archaean (c. 3,800–2,500 Myr ago) was still a great unknown in the earth sciences. This situation has changed dramatically since the 1960s as a result of two main factors: (i) advances in isotope dating methods and their application to Precambrian rocks, and (ii) the recognition that the oldest exposed gneiss and greenstone terrains retain a wealth of primary igneous, sedimentary and geochemical features.

It was clearly difficult to find an accurate title for a book which contains 13 miscellaneous contributions to a wide field, ranging in style from reviews to research papers and arguably more suited for publication in journals. Thus the principles of geochemistry were no different during the Archaean than they are today. Some workers (including myself) even consider that Archaean continental crust originated and evolved by processes closely similar to those of geologically recent times, albeit much more rapidly because of greater terrestrial radiogenic heat

The Ecology of Rocky Coasts

Edited by Dr P G Moore and Dr R Seed

This is probably the most comprehensive volume on the subject of the ecology of rocky coasts ever published. The book is the work of 28 internationally outstanding experts in the field and includes the most recent research and evaluations in this increasingly important area. It provides a complete overview of littoral and sub-littoral communities which will be of immense value to ecologists and marine biologists.

production. The deep crustal level represented by many Archaean rocks now exposed at the surface conveniently gives us insight into the chemical and petrogenetic processes occurring in the deeper reaches of the continental crust, not normally observable at those accreting or colliding plate margins where young continental crust is nowadays being created or reworked.

Certain aspects of the subject are efficiently dealt with in this useful volume, whose stated aim is to summarize some of the main issues in the broad geochemistry of Archaean rocks which were addressed during a nine-year stint of one of the projects ("Archaean Geochemistry") of the International Geological Correlation Programme. Topics range from the accretion history of the Earth and composition of the primordial mantle to greenstone belt evolution, petrogenesis of komatiites, the nature of high-grade gneiss terrains and the role of fluids in their development and geochronology, and the relation of Archaean sediments to the overall composition of the Archaean continental crust. Also included are geochemical and geochronological data on regions in the Soviet Union, China and India which were hitherto little known in the Western literature. It is refreshing, for once, to see some reliably documented new isotopic age data from the oldest shield areas of the Soviet Union to which up-to-date analytical and interpretative techniques have been applied.

I regret the absence of a contribution on the rapidly developing field of biogeochemistry and related topics, since the Archaean saw the transformation of "primordial soup" into the highly organized, far-reaching second course. Some discussion of Archaean metallogenesis would also have interested geochemists. □

Animal cognition

Geoffrey Hall

Animal Intelligence. Edited by L. Weiskrantz. Clarendon: 1985. Pp. 223. £32.50.

THE publication of this work (the proceedings of a Royal Society discussion meeting) just over a century after the appearance of *Animal Intelligence* by G. J. Romanes tempts one to make comparisons. Romanes was interested in animal intelligence because he felt the findings of comparative psychology had as much relevance to Darwinian theory as did those of comparative anatomy.

Romanes would be at home with Jerison's contribution to the present volume, a chapter which charts the evolution of encephalization and the implications of brain size for mental activity. But, as Jerison points out, little use is made elsewhere of evolutionary theory in organizing the wide range of facts about animal behaviour presented by the various contributors. One of the reasons for this neglect may be discerned in the chapters by Macphail and by Mackintosh and his collaborators. Although Romanes felt able to rank the various animal groups according to their level of intelligence (his scheme is reproduced in Weiskrantz's introductory chapter), modern experimental studies of animal learning (such as are reported by Mackintosh) have found precious few differences between species that can be unambiguously interpreted as being the result of differences in intelligence. Macphail concludes that we might as well accept what he calls the "null hypothesis" — that extant non-human vertebrates do not in fact differ in intelligence.

Romanes has been castigated by subsequent comparative psychologists for basing his conclusions on mere anecdote rather than on careful observation and experiment. To some, Macphail's conclusion may seem not so much an accurate judgement of the intelligence of animals as a condemnation of the skills of modern experimenters. And certainly, some of the most striking examples of intellectual achievement among animals reported in this book come not from laboratory studies but from observations made in natural or semi-natural conditions. Goodall concludes her intriguing survey of the innovative behaviour displayed by the chimpanzees of Gombe with an assertion of the value of (carefully documented) "anecdotal" reports of natural behaviour.

However this may be, none would deny the need for experimental analysis in any attempt to determine the mechanisms responsible for seemingly intelligent behaviour and much of this book is devoted to reports of such work. Several chapters present accounts of the behaviour shown by primates when solving the problems set for them by experimental psychologists. It

is made clear that their behaviour cannot be interpreted simply as the acquisition of new habits and must require intelligence of a higher order. But perhaps this has never really been in doubt. More significant, therefore, is the elegant analysis presented by Dickinson of the mechanisms by which that least esteemed of animals, the laboratory rat, learns the simplest of tasks, that of pressing a lever to obtain food. What emerges is a need to allow the rat knowledge about the relationship between its actions and its desired goals, and credit it with the ability to carry out inferences on the basis of that knowledge. No more than this is claimed for the primates, a fact that not only speaks in favour of Macphail's "null hypothesis" but also helps to justify the belief that has sustained so many studies of animal learning — that the study of cognitive processes in one vertebrate species will reveal principles of intellectual functioning that have general applicability.

It would be a disappointment if such general principles as emerge were to be found not to apply to our own species. But the possibility remains that human intelligence is different in kind from that shown by non-human animals, being based on our possession of a form of language that is beyond the capacity of any beast. Empirical investigation of this hoary notion long seemed impossible. But perhaps the most interesting implication of the recent attempts by several experimenters (Terrace, Gardner and Gardner, Savage-Rumbaugh and others are represented in this book) to teach a form of human language to an ape is that their work appeared to allow just such a possibility. Unfortunately, the outcome has been inconclusive. There is no real consensus as to what the apes have actually achieved or, more worrying, as to what it is that they would have to do in order for us to be sure that they had learned a language. An empirical solution seems as far away as ever.

More generally, this book leaves one with the impression of a field of study that is productively active, has achieved much in the hundred years since Romanes and is likely to achieve more in the near future. And this is only half the story. Romanes devoted roughly half of his book to the intellectual achievements of invertebrates. That these animals receive no mention in the present volume is its only serious failing. It is now becoming clear that the application of methods of study and analysis previously applied only to vertebrates can reveal evidence of equivalent intellectual sophistication in invertebrates. Our rapidly advancing knowledge of invertebrate neurophysiology fosters the hope that a comprehensive account of the biology of intelligence is almost within reach. □

WAVELENGTH METERS

For Use With HIGH REPETITION RATE PULSED LASERS

Hovemere Ltd. (UK) announce a range of wavelength meter systems which measure the exact wavelength of a pulsed or continuous laser source with a wavelength precision of 1 part in 100,000,000. The instrument provides real-time wavelength measurements for each pulse at repetition rates of up to 30 pulses per sec.

The wavelength meter is based on an ultra-stable Fabry-Perot interferometer, and the instrument can be run from any of the IBM-PC range of personal computers, or strict compatibles. Data output (mean wavelength, spectral line profile, peak and/or total pulse intensity) are available within the PC memory, or can be transmitted via serial or parallel protocols to a second computer. This second computer may, for example, be the user's controller for the laser and detector system.

Laser detection systems are also available for the near UV to near infra-red spectral region. Software packages are available to run a complete laser, wavelength meter and detector system, from a single computer such as the IBM PC-AT, or COMPAQ DESK-PRO, or the DEC PDP-MICRO-11 family. These software packages include graphical support for monitoring the performance of the laser, wavelength meter and detector, and for data analysis and storage/retrieval.

For extremely accurate wavelength measurement, over a limited absolute wavelength range, a single interferometer unit can be used. A triple-unit system can monitor pulse by pulse laser spectral output variations (intensity/wavelength jitter) over an extended wavelength range, and provide absolute values of the wavelength.

Laser Light Scattering Systems

for particle size analysis, molecular weight measurement and other applications

Malvern Instruments offer the most comprehensive range of laser light scattering instruments for characterizing fine particles and macromolecules.

SYSTEM 4700 is an advanced modular system designed to meet a wide range of applications in research and development laboratories. It features the new Malvern K7032 Multi-bit correlator with fast 16-bit computer processor and full range of software for photon correlation spectroscopy and total intensity light scattering measurements.

Malvern also make laser systems for routine measurements of particle size from submicron to 1800 microns and for zeta potential measurement by microelectrophoresis.

The Leader
in Laser Technology

 **Spectra-Physics**

Reader Service No.47

Spectra-Physics is the world's number one commercial company and covers more laser technologies and applications than any other company. Even more impressive is the fact that we have held this position at the top of the laser industry ever since the introduction of the first commercial gas laser in 1962. Today, we are the leader in lasers for the scientific market, in multi-kilowatt industrial CO₂ lasers, pioneers in lead-salt diode lasers, producer of the highest quality precision optics and coatings – and we are continually innovating, bringing new technologies to the market. A typical example is our series 2000 water-cooled ion laser offering significantly higher value in terms of durability, performance, and economy. With its unsurpassed output power, it is ideally suited to a wide range of laboratory applications such as Laser Doppler Velocimetry, holography, cell sorting and Raman spectroscopy...

Birth of the maser and laser

Shortly before his death in January 1984, Professor Alfred Kastler, winner of the Nobel Prize for physics in 1966 for his work on optical pumping, submitted to Nature a book review of Masers and Lasers by Mario Bertolotti¹. Published here is an edited and abridged version of the review.

THE word 'maser' was coined by Townes in 1951, as the acronym of 'microwave amplification by stimulated emission of radiation', and 'laser' was formed in the same way, 'light' replacing 'microwave'. In their famous *Physical Review* paper of 1958², Schawlow and Townes had used the term 'optical maser', a linguistic nonsense since it would literally mean 'optical microwave amplification...'. Incidentally, the most valuable property of these devices is not amplification, though they are widely used for this purpose in the microwave and optical regions, but self-sustained oscillation, so we should arguably call them 'mosers' and 'losers'!

The subject is, however, much older than the maser and the laser. Its prehistory began in 1916-17 with two papers by Einstein^{3,4} in which the distinction between spontaneous and induced emission of radiation was made. Both processes were shown to occur not as spherical waves, familiar from Maxwell's theory, but as a highly directional form of radiation (*Nadelstrahlung* rather than *Kugelstrahlung*, as Sommerfeld put it in 1922), the spontaneous emission having the same direction as the stimulating light and accentuating its intensity (negative absorption). The emission cannot, however, be in phase with the stimulus, for this does not permit conservation of energy; instead, the atomic emitters must be a quarter-period ahead of the driving field, as experimentally verified by Meslin. Einstein made no mention of the coherence of the stimulated emission, and it is tempting to speculate that this delayed the invention of the laser.

The exchange of momentum between atoms and light is clearly crucial and Einstein had examined this in great detail as early as 1909. As a working hypothesis, he suggested that light may be regarded as particles (our photons), which are to be thought of as local singularities in which the electromagnetic field energy is concentrated. These 'particles' are guided by the electromagnetic wave, interacting as they proceed. In Einstein's mind, therefore, wave properties such as interference and diffraction are a collective property of these particles. The richness of this idea in studies of both light and charged particles cannot be overstressed.

The important connection between the absorption and emission of light and the phenomenon of anomalous dispersion is perhaps not quite so obvious. The dispersion formula of Kramers and Heisenberg (1925)⁵ in fact contains 'negative dispersion' terms, which are connected with 'negative absorption' or, in other words, stimulated emission. The existence of these terms was demonstrated experimentally by Ladenburg and co-workers; in particular, Ladenburg and Kopfermann^{6,7} found that on raising the current density in a neon discharge, the negative dispersion terms grew more important, the temperature corresponding to the population ratio of the energy levels involved reaching values far higher than the kinetic temperature of the atoms and electrons. Had these authors continued their investigations and extended them to argon, they would probably have attained population inversion (a prerequisite for laser and maser action, to which I will return later). As Bertolotti mentions, Schawlow later thought it likely that Ladenburg and Kopfermann "did not continue their studies on anomalous dispersion because they believed so firmly in equilibrium that they thought it was impossible to go so far away from it as to have negative absorption"⁸.

In the 20 years that separated the 1930s—by which time the concepts of stimulated emission and negative absorption had become well established—and the invention of the maser and laser, the problem of magnetic resonance was solved and the process of optical pumping introduced. Although not directly relevant, the knowledge acquired was later useful in the development of lasers. Incidentally, Bertolotti's short note on the history of the classical theory of magnetism fails to mention Pierre Curie's thesis on the magnetic properties of matter, completed in 1895; he also wrongly credits Pauli with developing the concept of 'spin' in 1920 (see box), but the complex history of the different types of magnetism demands a fuller account than is given in the book.

In the early 1950s, prehistory ended and history began. The maser principle was developed independently at Columbia University (New York) by Townes, at the Lebedev Institute (Moscow) by Basov and Prokhorov and in the University of Maryland by Joseph Weber. It was at a conference in Ottawa in 1952 that Weber first mentioned publicly the principle of the maser, the text of his lecture appearing in print a year later⁹. The work of Townes and colleagues on the ammonia maser appeared in 1955¹⁰, a year after the first publication on the subject by Basov and Prokhorov, who, as Bertolotti notes, "pointed out the theoretical possibility of a device producing microwaves by using stimulated emission at an All-Union conference on radiospectroscopy in May 1952, but ... their first written paper was not published until October 1954"¹¹.

To generate coherent electromagnetic radiation, three conditions must be satisfied: stimulated emission, strong enough to surpass the absorption of the medium, must be obtained; a suitably inverted population must be created; and a convenient cavity must be used. In fact, the first two conditions are identical. As far as the last one is concerned, the cavity in the microwave region is just a suitably shaped metal box. The latter usually has the form of a cylinder closed at one end by a piston so that the proper mode of oscillation can be matched to the frequency of the atomic or molecular transition. Single-mode operation is easily achieved.

In the case of lasers, the appropriate cavity is a Fabry-Perot interferometer, as Schawlow and Townes pointed out in their fundamental paper of 1958², and if any French contribution to the laser deserves mention this is it. Fabry and Perot developed their instrument at the University of Marseilles in the early years of the century¹². The cavity of this device is cylindrical and the diameter of the two parallel circular faces is conventionally greater than their separation. Here I should digress briefly to say a word about R. Boulouch, who was a precursor of Fabry and Perot. In 1893 he published a description in the *Journal de Physique*¹³ of the very fine fringes he had obtained with thin silver layers, and mentioned that, for a suitable value of the distance between the reflecting surfaces, he had been able to separate the components of yellow sodium light: "Les anneaux dédoublés apparaissent, pour une épaisseur convenable de la lame, singulièrement nets" (for a suitable choice of the thickness of the plate, the two ring systems are remarkably distinct); he also noted that the line-shape could be explained in terms of the Airy function. Boulouch was at that time a grammar-school teacher at the Lycée of Bordeaux, where I myself taught in the years 1929-31, and where I met the elderly Boulouch, by then

Kastler's views on Pauli's contribution

BERTOLLOTTI is mistaken when he attributes the development of the concept of 'spin' to Pauli in his 1920 paper. This paper deals with the quite different problem of paramagnetism. 'Electron spin' was in fact discovered in 1925 by Uhlenbeck and Goudsmit. Why did this concept become necessary to atomic physicists? The extensive study of fine structure of spectral lines and the related anomalous Zeeman effect obliged physicists to introduce a new quantum number to stand alongside the principal quantum number n , which determines the energy of an atomic state, and the azimuthal quantum number k , which gives the angular momentum of a state, both in units of Planck's constant h and both being integers. (Today we use l where $l=k-1$.) The third quantum number, which we represent by the letter j , sometimes takes a half integer value—this came as a surprise at the time—the vector representing the total angular momentum of the atom.

In a lecture given in Germany in 1965, when he was awarded the Planck medal, Samuel Goudsmit gave his personal version of the discovery of 'electron spin'. He cited a passage from a letter sent to him in March 1926 from Copenhagen by his friend and colleague L. H. Thomas. In this letter Thomas writes: "I believe that you and Uhlenbeck had the good luck to see your spinning electron published and discussed before Pauli knew of it. More than a year ago Kronig had conceived the rotating electron and had developed his idea; Pauli was the first person to whom he showed this paper. Pauli told him that it was a ridiculous assumption, and so it happened that the first person to see Kronig's paper was also the last one." And Thomas concludes the story by stating: "All this shows that God's infallibility is not extended to whom had nominated himself to be his vicar on earth." German

physicists have since composed the rhyme: "Der Kronig hatt 'den Spin entdeckt, Hatt' Pauli ihn nicht abgeschreckt." (Kronig would have discovered spin if Pauli had not discouraged him.)

There is another reason why Goudsmit adopted a very critical attitude towards Pauli. In his Nobel lecture of 1945 Pauli gave an explanation of the hyperfine structure of spectral lines by postulating the existence of a nuclear spin whose magnetic moment interacts with the moment of the electron cloud, an idea which he had published in 1924. He claimed that this publication had influenced Goudsmit and Uhlenbeck in their claim of an electron spin. Goudsmit maintained that Pauli had never considered an internal moment of the nucleus. He had especially not foreseen it for the proton. For him the nuclear angular momentum, with its small associated magnetic moment, was due uniquely to the orbiting electrically charged particles inside the nucleus, namely the protons and, as was assumed at that time, the electrons. So the discovery of electron spin as an internal momentum owed nothing to Pauli.

Pauli, in his young years, had been a severe judge for the physicists of his generation who feared his sharp criticism, and as we have seen his influence on the development of physics was not always a positive one. I made his personal acquaintance some years before his untimely death, meeting him at the Physics Summer School of Les Houches and in Varenna. In those days he had become a friendly and indulgent person. His exclusion principle, on which are built Fermi-Dirac statistics and the explanation of the shell structure of the electrons in an atom, remains a great achievement in the development of physics. □

retired. During 1889 and 1890, Charles Fabry had also taught at this same lycée, and had been a colleague of Boulouch, but he never mentioned the priority of Boulouch's researches. So far as I am aware, only Tolansky cites Boulouch's work, and he gives the wrong reference (1906 instead of 1893)¹⁴.

Let us now consider how population inversion was obtained. In Townes's first ammonia maser, molecules were excited into a higher energy state by means of a molecular beam, the molecules being separated by an inhomogeneous electrical field. Many celebrated experiments have used this atomic beam technique, but how many people remember that it was invented by Louis Dunoyer in Paris in 1919? Another elegant method of obtaining population inversion in the microwave region was exploited in Bloembergen's three-level maser. Some six different procedures have been used to trigger off laser action; it has often been found surprising that a simple gas discharge can create the necessary non-equilibrium state, as it does in the argon laser. Among the other methods, we recall electron impact, chemical reaction and Javan's proposal of 1959, which led to the first gas laser able to operate continuously, using two gases, and which was subsequently exploited in the high-power CO₂ laser. Bertolotti discusses all of these techniques thoroughly in Chapters 4, 5 and 6 of his book.

Finally, optical pumping can be used to obtain population inversion and it was in this way that Maiman operated the first laser, relying on the chromium ions in a ruby crystal¹⁵. Perhaps I can give my own version of the story. Optical pumping techniques were developed in my Paris research group during the period 1950-70 by a dozen young and enthusiastic research students under the guidance of Jean Brossel. It was this collaborative work that was the origin of my Nobel prize. In the very first paper in the new journal *Applied Optics*¹⁶, Francis Bitter surveyed this development and Jean Brossel has also given us his view of the story¹⁷. Ground-state optical pumping had been preceded by the double-resonance method, in which optical resonance produced by light is combined with magnetic resonance generated by a radiofrequency coil. As Bertolotti mentions, the Italian physicists Fermi and Rasetti had applied an oscillating magnetic field to atoms at optical resonance as early as 1925

and observed an oscillating Hanlé effect (depolarization of the resonant light). In his *Note e Memorie di E. Fermi*¹⁸, quoted by Bertolotti, Rasetti describes how

Fermi pointed out that, since the mercury resonance line showed an anomalous Zeeman effect with a Landé factor of 3/2, the mercury atom should more likely precess with a frequency 3/2 times higher than the Larmor frequency. The choice between the two alternatives might be decided by investigating the behaviour of the polarization under magnetic fields, of the intensity of about one gauss and a frequency of a few megacycles per second in approximate resonance with the precession frequency of the atom.

It thus seems that in 1925 the idea of Brossel's double-resonance experiment had already occurred to Fermi, but the fields applied (1-2 G) were insufficient to produce any appreciable resonance.

Brossel and I arrived at this method independently after an exchange of letters about the failure of attempts to investigate an excited state of mercury by Bitter's method; Brossel was working in Bitter's laboratory at Massachusetts Institute of Technology (MIT) at the time (1949). We published the principle together¹⁹, after which Brossel went on to perform the corresponding experiment and published the result. In my 1950 paper²⁰, I suggested altering the population of the magnetic m -states in the ground-state of the atoms by irradiating them with polarized light; if the polarization was linear, a change would be produced between states of large and small m (alignment), while if the polarization was circular (left- or right-handed), concentration of the atoms in either the negative or positive m -state (polarization magnetization of the ensemble of atoms) would be favoured.

As a young student, I had the opportunity of visiting Germany in 1922, where I bought Sommerfeld's book. I read it eagerly, being especially interested in the section on the "Auswahlprinzip und Polarizationsregel" ("selection principle and polarization rule") in which the thesis of Sommerfeld's Polish research student A. Rubinowicz is summarized. Optical pumping is just an application of this principle and rule.

In 1951, Brossel returned to Paris after six years abroad, three with Tolansky in Manchester and three with Bitter at MIT.

(British and American scientists may find it difficult to imagine the state of scientific isolation in France during the war years; we were cut off from the Allies and had no desire for contact with German scientists.) Brossel had a good idea of the progress of science abroad and knew what equipment we should need to resume our research, essentially oscillators and photomultipliers to develop the double resonance and optical pumping techniques. Our expenses were defrayed by the French Centre National de la Recherche Scientifique.

I am grateful to Bertolotti for recalling that we never intended to work on stimulated emission. Our aim was to change not the energy but the angular momentum of atoms, either in their ground state or in their excited states, thereby detecting magnetic resonance transitions which could be measured with high precision. My Nobel prize was given for the development of the optical methods of radiofrequency resonance (the 1964 Nobel prize in physics having been awarded to Townes, Basov and Prokhorov, the pioneers of the maser and laser). Despite this, my photograph appeared on the cover of a weekly journal with the caption "the father of the laser". I refuted this immediately in an address before the French Academy of Sciences, but there seems no way of suppressing this *canard* which continues to reappear intermittently. I deeply regret that Jean Brossel did not share the Nobel prize with me.

Bertolotti continues with an account of recent developments, the construction of the free-electron laser for example, and in

a concluding chapter examines the statistical properties of light, which are very different for coherent and incoherent radiation; this material is more demanding mathematically than the earlier parts of the book.

It is a pity that there was not room to give a more popular account of the applications of lasers and masers, which have become marvellous tools, in physics of course, but also in metrology, astronomy, medicine and industry, not forgetting the laser light that reads compact disks. The author alludes only briefly to such applications, observing that the field is "still open today"—perhaps the best applications are still to come? The role of the laser in turning Gabor's proposal of holography into a reality is briefly mentioned. Let us hope that the newer high-power lasers will never be used as weapons in outer space. Lastly, a word to the publishers: it would have made things much easier for the reader if the notes and references had been grouped at the end of the book, instead of having to be hunted for at the end of each chapter.

Let me not end on a negative note, however. Professor Bertolotti's book is a fascinating account of the history and prehistory of the maser and the laser. Most readers will enjoy his thumbnail sketches of the scientists involved, for his book tells us not only about physics but also about physicists, a very attractive feature. Although it is not aimed at the non-scientist, scientists from other fields will be able to follow the story since complicated mathematical reasoning is usually avoided.

High-power solid-state lasers

J. F. Holzrichter

Lawrence Livermore National Laboratory, Livermore, California 94550, USA

Laser power has increased by 11 orders of magnitude since Maiman's first demonstration of 10^3 W in 1960. Present high-power solid-state laser systems have been irradiating targets with 1–10 terawatts of power in 1-ns pulses at wavelengths varying from 1.05 to 0.26 μm . The Nova laser is beginning experiments in the 10 to 100-terawatt range. There are numerous possible means of extending solid-state technology to the 500 to 1,000-terawatt level and to efficient, high-average-power operation.

THE prospect of constructing lasers having peak powers greater than 10 TW excited the interest of experts in thermonuclear reactions in the early 1960s¹. This power, when focused to intensities of $\sim 10^{14} \text{ W cm}^{-2}$ onto small capsules containing deuterium and tritium fusion fuel, was thought to be capable of generating thermonuclear reactions^{2,3}. Other applications considered at the time included the optical pumping of X-ray lasers, and equation-of-state and other atomic-physics measurements at high temperature and density. Efforts to construct lasers powerful enough to demonstrate these concepts have been extremely successful (see Fig. 1): thermonuclear conditions in deuterium-tritium (DT) fuel are being attained⁴, stimulated emission at soft-X-ray wavelengths has been observed^{5,6}, and a variety of other measurements are being accomplished⁷.

Laser power has increased by 11 orders of magnitude, from Maiman's 1960 Q-switched ruby laser⁸, which produced ~ 1 kW, to the Nova laser, which can produce up to 100 TW (Fig. 2). In the 1960s the invention of mode-locking led to the generation

of laser pulses as short as 10^{-11} s, and Nd:glass gain media capable of amplifying these short pulses to moderate energies (~ 100 J) were developed. The appropriate combination of these technologies yielded lasers producing nearly 100 GW. The physics of these systems was incompletely understood, however, and while laser-target experiments were enticing, the results were erratic. By 1971, programmes were conceived to build 10-TW lasers to demonstrate inertial confinement fusion (ICF) concepts at spatial scales large enough to ascertain the potential for generating efficient thermonuclear burn⁹.

Inertial confinement fusion research

In 1971, three laser media—atomic iodine, CO_2 and Nd:glass—were available for scaling to laser sizes capable of producing 10 TW (that is, 10 kJ of energy in pulses shorter than 10^{-9} s). The atomic iodine laser system was not chosen for development in the national laboratory programmes in the United States because the diagnostics were somewhat difficult at the laser

Fig. 1 Laser systems have increased dramatically in peak power since 1960. The laser names before 1980 are Livermore systems although other laboratories contributed significantly to this progress. Lasers in the 10-TW category were Shiva and Novette, the two-beam precursor to the 10-beam Nova system. Gekko XII, a 12-beam laser delivering 50 TW at $1\ \mu\text{m}$ or 20–50 TW at $0.5\ \mu\text{m}$, is beginning experiments at Osaka University. Omega is a 24-beam (12-TW, $1.0\text{-}\mu\text{m}$) laser system at the University of Rochester, recently converted to 4 TW at $0.35\ \mu\text{m}$. The high-gain and reactor facility boxes show the objectives of high-power laser design.

wavelength of $1.3\ \mu\text{m}$ and because there was little experience in generating sub-nanosecond laser pulses⁷. The potential of the CO_2 laser to generate laser pulse energy with an efficiency of $\sim 10\%$, and its high-average-power capability for possible reactor applications, made it an attractive candidate. But the coupling of $10.6\ \mu\text{m}$ CO_2 laser light to dense target plasmas occurs at electron densities of $10^{19}\ \text{cm}^{-3}$, where electron-ion damping of plasma instabilities is weak, making the production of a very nonthermal plasma, unsatisfactory for inertial fusion applications, a distinct possibility. The attractiveness of the CO_2 laser system, and uncertainty over the seriousness of these plasma problems, led the group at the Los Alamos National Laboratory to develop CO_2 lasers having outputs of 10 TW (the Helios laser) and 30 TW (the Antares laser system) (ref. 9; see also similar

reports from the Los Alamos National Laboratory, 1971 to present).

At the Lawrence Livermore National Laboratory (LLNL), the Nd:glass laser was chosen as the major tool for research into the laser-plasma interaction¹⁰. Attractive features of the neodymium system are the ease with which pulse duration and pulse shape can be varied, the high optical-damage thresholds (which lead to moderately compact systems), the conveniently available beam diagnostics using film, silicon detectors or vidicons, and the scalability (through increased beam area or multiple beams) to high powers, which now exceed 100 TW and which can reach 1,000 TW. A variety of very efficient harmonic conversion techniques were also invented for this system, and these have been used to produce laser energy for a wide variety of experiments at 0.53 , 0.35 and $0.26\ \mu\text{m}$ (refs 11–13).

During the 1970s, experimenters used these systems and showed that both $10\text{-}\mu\text{m}$ and $1\text{-}\mu\text{m}$ laser wavelengths are too long for effective plasma heating. Studies using light at 0.5 , 0.35 and $0.26\ \mu\text{m}$ from harmonically converted Nd:glass lasers showed satisfactory plasma heating and confirmed earlier simulations. As a result, most ICF research is now being conducted with harmonically converted Nd:glass lasers. This research is being done in the United States at KMS Fusion Inc., Lawrence Livermore National Laboratory, the University of Rochester and the Naval Research Laboratory; in Europe at the Rutherford Laboratory and the Atomic Weapons Research Establishment, Aldermaston (both in England); at CEA Limeil in France; at the Lebedev and Kurchatov Institutes in Moscow; at the Max Planck Institute in Garching, FRG; and in Japan at Osaka University.

Research to provide other sources of short-wavelength light is also progressing. This work centres on the krypton fluoride laser¹⁴, with output at $0.249\ \mu\text{m}$, and the harmonically converted atomic-iodine laser^{7,15}, with outputs at 1.3 , 0.65 , 0.44 and $0.32\ \mu\text{m}$. These systems are being developed at several laboratories, but they have not yet been used for target experiments at multiterawatt levels.

While it is now clear that Nd:glass laser technology will suffice for the necessary laser-plasma research, it was thought necessary to invent a separate high-average-power, efficient laser technology for potential commercial applications. This process has been ongoing since the mid-1970s; there is not space here to review progress in this area. One surprising result of these studies, described in ref. 16, is the extent to which advanced solid-state systems, building on Nd:glass technology, may play a role.

Fig. 2 *a*, The 10-beam Nova laser will provide 80–100 TW of peak power at $1.05\ \mu\text{m}$ and 40–70 TW of power at 0.53 or $0.35\ \mu\text{m}$ for fusion experiments. The pulse duration (and pulse shape) is variable from 70 ps to >10 ns. *b*, The target chamber. The large barrels attached to the target chamber contain the harmonic conversion arrays and the focusing lenses.

Fig. 3 The Nova laser beam is expanded, spatially filtered and re-imaged (projected) from a smaller amplifier section to the next larger section. Interchain peak (solid line) and average fluences (dots) as a function of distance along the laser chain, are shown for a 10.5-kJ laser pulse 1 ns long. The sizes and locations of the spatial filter lenses are indicated along the top of the figure. Entrance-lens surfaces will suffer damage if the peak fluence exceeds the indicated limits.

Laser physics and design

The physical constraints that control laser operation at 10 TW are reasonably well understood, and recently constructed systems have been designed to accommodate them¹⁷. These constraints are associated with the generation and shaping of the initial laser light pulse, the production and control of gain (and loss), the control of linear and nonlinear propagation along the beam path to keep the beam highly focusable, and the harmonic conversion of the high-power fundamental laser wavelength. Additional engineering concerns include cost, maintenance, and the diagnostics and control of the laser-target system.

The design of present Nd:glass lasers aims at realizing gain and propagation performance as close as possible to physical limits. While we use the Nova fusion laser as an example¹⁸, the design of high-power laser systems based on the other media is subject to similar constraints.

The amplification of a 10^{-4} -J, 1-mm-diameter oscillator pulse to a $\sim 10^4$ -J, 74-cm beam is accomplished by paying careful attention to the optical properties of the laser media and the optical system. Astronomical telescopes are used to enlarge and project the laser beam from the oscillator to the target-focus lens. The telescopes also project and image the beam shape from one stage to the next down the chain¹⁹; this prevents the beam shape from diffracting and developing highly modulated

diffraction 'ripples' as it propagates. That is, a well-shaped (apodized) beam that effectively fills the laser aperture can be magnified, projected through each laser amplifier where it is intensified, then further magnified and amplified in the next stage until it reaches the desired energy (consistent with the optical-damage threshold of the final element and with nonlinear self-focusing limits), and projected and amplified again (see Fig. 3). The telescope also serves a second important function, that of spatial filtering¹⁹. At the focus of the telescope system the laser beam is passed (in vacuum) through a pinhole that removes the high-frequency spatial noise from the beam. A second telescope lens then recollimates the expanding beam and projects a 'smoothed' image of the input aperture a distance Mf further downstream, where M is the magnification and f the length of the spatial filter. (A consequence of this approach is that the long distance travelled by the beam in Nova-like lasers is mostly through telescopes.)

The laser gain is determined by the stimulated-emission cross-section of the laser medium, by the pumping-rate limits set by the power supply, and by one of two gain-limiting processes. The first of these processes is stimulated depumping by amplified spontaneous emission (ASE) and the second is feedback oscillation (usually unexpected) from reflecting sources such as metal lens holders, screwheads, or the walls of the amplifier case. Stimulated depumping occurs when a spontaneously emitted photon traverses the gain medium and stimulates other ions to de-excite, thus depumping the medium. When the 'gain-coefficient $\times$ gain-length product (αl)' in the laser medium exceeds 4.5, this rate approaches 30% of the pumping rate for usual pumping situations. A greater loss rate than this is undesirable. Furthermore, at such a gain level, $G = \exp(4.5) = 90$, a 1.1% or larger reflection can cause a parasitic oscillation to start. This is avoided in glass lasers by cladding the edges with an index-matching absorbing glass yielding $<10^{-3}$ reflectivity. In the largest Nova amplifier (see Fig. 4), the laser plates are also cut and clad along the middle to control the transverse gain path and thus the ASE loss.

The efficiency of gain production is a complex function of the power-supply to gain-medium transfer efficiency (typically 1%) and the gain-medium to laser-light transfer efficiency (typically 25%). In research lasers, system efficiency is important only insofar as it (and the per-unit cost of power-supply) contributes to the total system cost. The very low cost of flashlamps and discharge capacitors compensates for the present low efficiency to provide acceptable power supply costs. However, for commercial applications such as the production of electricity or nuclear fuel, system efficiencies near 10% would be necessary²⁰.

Gain is developed when Nd^{3+} ions in optical glass plates are pumped by xenon flashlamps for 600 μs duration in an amplifier structure (Fig. 4). The gain coefficient α in the glass in the larger

Fig. 4 The neodymium glass plates are mounted at Brewster's angle with respect to the laser beam to provide zero reflection loss. Light from the flashlamps excites the Nd^{3+} ions to produce gain.

Fig. 5 High-power laser beams will self-focus when propagated at high powers through long glass paths. The criterion is given by the B -integral and by the spatial noise sources in the laser system. When spatially filtered, the beams are smoothed so that further propagation is possible. *a*, Into the spatial filter; *b*, exit from the spatial filter.

amplifier is typically 0.05 cm^{-1} , so that the beam must traverse a total path of 45 cm in the gain medium to reach a gain of 10. Ten 4-cm plates set at Brewster's angle in a series of disk amplifiers like those shown in Fig. 4 are used to provide the gain path in this amplifier stage. Six stages of amplification are used in each beam line to amplify the beam from 1 J at the entrance to 10^4 J at the exit.

As the beam propagates down the laser chain, its phase front is modified by linear and nonlinear phase aberrations. Linear aberrations cause small modifications to the phase front that reduce the focusability of the beam on the target. The optical glass in which the neodymium ions are dissolved can be made homogeneous to 2 parts in 10^6 , which would yield approximately 2 waves of aberration per metre of path in glass. Present polishing techniques are capable of compensating for these aberrations: when the beam passes through the 150 surfaces and 3 m of glass in a Nova laser beam, an acceptable 2–3 waves of total linear aberration result.

The most nonlinear (and permanent) impediment to beam propagation is optical damage. The energy fluence in the beam, $5\text{--}10 \text{ J cm}^{-2}$, is enough to cause the explosion of small absorbing inclusions in coatings or within laser glass or lenses, obscuring part of the beam and permanently damaging the laser component. Laser glass and other transmitting optics can be made inclusion-free², which will allow them to sustain intensities greater than $10^{10} \text{ W cm}^{-2}$ in 1-ns pulses. However, to obtain good production yields of inclusion-free glass for reliable operation at these fluence levels, additional work is required. A great deal of effort has been expended on developing coatings that can withstand operation at high fluence. Particularly successful anti-reflection coatings based on 'sol-gel' coating technology and on 'neutral-solution' surface etching processes have been produced and used in the Nova laser²¹. These coatings are virtually defect-free and exhibit damage thresholds three times higher than those produced using electron-beam deposition procedures.

A more gradual nonlinear beam limit is caused by self-focusing¹⁷. At intensities $>10^9 \text{ W cm}^{-2}$, the electric field of the laser beam exceeds 10^6 V cm^{-1} . This field is strong enough to modify the electron orbits around the atoms or molecules in the medium through which the beam propagates, changing the index of refraction. This causes a self-focusing instability to grow at a rate proportional to $\exp(2B)$, where B is the so-called breakup or B -integral

$$B = 0.026 \frac{n_2}{n\lambda} \int I \, dl \quad (1)$$

Here n and n_2 are, respectively, the linear and nonlinear indices of refraction in electrostatic units, λ is the laser wavelength in μm , I is the intensity in GW cm^{-2} , and dl is the element of path length in cm. The breakup integral must have a value less than ~ 3 for propagation to occur without severe loss. The nonlinear index of refraction changes the index of refraction by $\sim$ one

part in 10^6 at peak intensity. This change is small (it corresponds to less than one wave of beam phase retardation per metre of glass path traversed). But if the transverse dimension over which it takes place is small ($\sim 1 \text{ mm}$), the induced focal power of the resulting 1-mm-diameter 'lenslet' will cause a 1-mm portion of the beam to self-focus, and the corresponding energy will not be available for harmonic conversion or for focusing on a target (see Fig. 5). Nonlinear beam self-focusing was the chief cause of nonreproducibility in early laser-target experiments. In extreme cases, the entire laser beam self-focused into thousands of small light filaments that could not be focused on the target and which 'drilled' small holes in the laser glass, the mirror coatings and the lens surfaces. Control of nonlinear self-focusing made Nd:glass lasers useful for target irradiation and made them scalable to much higher power than was at first predicted.

To provide adequate gain and to control self-focusing, neodymium-doped phosphate glass was selected as the gain medium. Its gain characteristics are compatible with 5-J cm^{-2} output fluence, and its self-focusing characteristics permit the propagation of twice as much optical fluence as in silicate laser glasses. This permitted propagation at higher fluences through longer gain-medium paths than in previous fusion lasers, such as the Shiva laser at LLNL. The longer gain path is needed to amplify the laser pulse to the 5-J cm^{-2} (5-GW cm^{-2}) level at 1-ns pulse duration, or to 10 J cm^{-2} when the system is used for experiments with pulse durations $>3 \text{ ns}$. The lower nonlinear index of refraction of the phosphate glass permits high-power operation with very short pulses ($\sim 0.1 \text{ ns}$) also.

Harmonic conversion

Harmonic conversion is used to generate shorter wavelengths for target irradiation. This is feasible because of the high phase uniformity of high-power beams from modern lasers, and because the power density in such beams is high enough (GW cm^{-2}) to drive a nonlinear polarization in the atoms or molecules of non-centrosymmetric crystals. The magnitude of the linear polarization is

$$P = \chi \epsilon_0 E = 10^{-4} \text{ debye per molecule per GW cm}^{-2} \quad (2)$$

where χ is the susceptibility, ϵ_0 is the vacuum permittivity, and E is the electric field of the light wave. If a non-centrosymmetric crystal is used, the restoring force on the electron cloud is not symmetric about the equilibrium position, and the susceptibility can become proportional to E :

$$\chi = \chi_0 - \chi_1 E + \dots \quad (3)$$

When equation (3) is substituted into equation (2), there results a term in the polarization, $\chi_1 \epsilon_0 E^2$, that leads to an oscillating dipole at twice the fundamental frequency ω_0 of the electric field. A typical $2\omega_0$ nonlinear polarization is 10^{-9} debye per molecule, or 10^{-5} times the linear polarization.

One can imagine this nonlinear polarization developing in the first plane of atoms in the crystal as the beam strikes the

Fig. 6 High-power, 1.05- μm laser beams are sufficiently uniform in phase to uniformly convert to 0.53, 0.35 or 0.26 μm with high efficiency. *a*, A 3×3 array of 1.8-cm-thick KDP harmonic conversion crystals. *b*, Conversion efficiencies with a similar array on the Novette laser.

surface. We can arrange for the radiated waves from each plane of atoms to add coherently to those of the succeeding planes, so as to generate a strong harmonic wave; we do this by choosing the propagation direction in uniaxial or biaxial crystals so that the phase velocities of the harmonic and fundamental waves are the same (the waves are then said to be phase-matched). Phase-matching allows for very efficient harmonic conversion when the phase front of the incoming fundamental laser light is uniform enough to maintain these conditions over the entire beam area and throughout the length of the crystal. For example, with a properly oriented 1.8-cm-thick crystal of potassium dihydrogen phosphate (KDP), we can convert 1.05- μm laser light at 2 GW cm^{-2} to the second harmonic at 0.53 μm with up to 80% efficiency¹¹⁻¹³. When losses in the optical components (lenses, diagnostics, blast shields) of a fusion laser beam line are taken into account, it is possible to deliver over 50% of the laser's 1.05- μm energy to a target at 0.53 μm ; 70% conversion efficiency may be expected with additional engineering improvements^{22,23} (Fig. 6).

By using a second crystal after the first crystal, efficient conversion to the third harmonic at 0.35 μm or the fourth harmonic at 0.26 μm is possible. For the third-harmonic process, the

Fig. 7 Amplitude pictures of 74-cm-diameter beams on Novette. The quality of these beams permits focusing to 100- μm -diameter focal spots, leading to power densities $>10^{17} \text{ W cm}^{-2}$ on target. However, most target irradiation is conducted at 10^{14} – $10^{15} \text{ W cm}^{-2}$. The dark vertical line in the middle of the beam is due to the gain-parasitic absorber in the largest amplifier. The 3×3 checkered pattern is due to the array of harmonic conversion crystals. *a*, 10 TW, 1.05 μm ; *b*, TW, 0.53 μm .

second crystal is oriented to phase-match a one-to-one photon mix of two input waves, one at 0.53 and the other at 1.05 μm , which beat together through the χ_1 term in equation (3) to produce the output wave at 0.35 μm . Experiments at Rochester and at Lawrence Livermore have demonstrated third-harmonic conversion efficiencies of up to 80% (refs 11–13). For the fourth-harmonic process, the second crystal is oriented to convert a 0.53- μm wave from the first crystal to 0.26 μm .

The Nova laser

The Nova laser was designed to be a versatile experimental system capable of irradiating targets with pulse durations from 0.05 ns to over 10 ns at wavelengths of 1.05, 0.53 and 0.35 μm (ref. 24). Experiments at 0.25 μm can be accomplished with some modification. In 1982, early production of two of Nova's 10 beams were configured into a facility called Novette^{22,23}, which was used to verify the Nova laser design and the process of harmonic conversion to 0.53 μm , and to verify models of plasma heating by 0.53- and 0.25- μm laser light. This work was largely successful²⁵. The objective of the full 10-beam Nova laser is to extend these results and produce conditions of DT-fuel compression and laser-plasma coupling similar to those required by high-gain targets.

The diameter of Nova's beams posed special problems for harmonic conversion. Our solution was to assemble slices cut from 27-cm-wide KDP crystals into a 3×3 mosaic array with a 74-cm-diameter aperture (see Fig. 6). A significant technological innovation was the use of a diamond cutting tool on a precision lathe to cut each crystal surface to the required smoothness and flatness and to the correct angle with respect to the crystal axes. In addition, it was necessary to develop coatings, mechanical supports and diagnostic techniques. The final harmonic system is remarkably simple, using advanced sol-gel coatings and a two-crystal design that efficiently generates 0.53 μm or 0.35 μm light with a simple tilt ($1/4^\circ$) and rotation (10°) of the array. A singlet-lens focusing system, using chromatic dispersion in the lens, together with a central beam block, can focus the beam at the fundamental 1.05- μm wavelength, or at the two harmonic wavelengths, without other, unwanted wavelengths reaching the target.

At the highest beam powers delivered by Nova, stimulated nonlinear optical processes can occur: stimulated Raman scattering from nitrogen in the beam path, additional nonlinear self-focusing in the air path, and transverse stimulated scattering in Raman-active materials (for example, the KDP crystals) were the expected possibilities. Careful measurements of the thresholds for these processes gave us confidence that the system would perform satisfactorily at the desired powers. With the Nova beams finished, we have now measured a gain of 2.7 cm per TW for stimulated Raman scattering in a very long beam

path²⁶. This gain is high enough to limit Nova's output power, so we are planning to remove the nitrogen from the beam tube. Nova's output in 1-ns pulses will be 80–100 kJ at 1.05 μm , with better than 50% conversion to 0.53 or 0.35 μm , depending on the pulse duration. Figure 7a, b shows the 1.05- and 0.53- μm beam images, respectively, from a Nova beam when it was used on the Novette laser.

Future developments

The future development of high-power solid-state lasers will follow two directions. A 5–10-MJ, 1,000-TW laser will be required to demonstrate and optimize the performance of high-gain ICF targets (see Fig. 1). A high premium will be placed on the versatility and cost of this system technology, and on the utility of the technology in future industrial, defense and ICF applications. The second direction is toward high average power and very efficient operation at moderate cost. Systems with these characteristics would be required for electrical power generation or for production of nuclear fuel.

Work on both types of systems is progressing. Considering our views in the early 1970s, we are surprised that the scale of the Nd: glass laser, as well as those of the I, KrF and CO₂ lasers, can indeed be increased so as to reach the energy and power

levels necessary for high-gain fusion demonstrations. The harmonically converted glass laser appears to offer the most flexible and economical approach to meeting this objective. This conclusion is based on the physics constraints of the competing systems and on the engineering and manufacturing experience developed in building large CO₂ and glass fusion-laser systems and smaller experimental KrF laser systems. The prospect of high-repetition-rate (5–10 Hz), highly efficient (>10%) solid-state lasers using crystalline hosts rather than glass hosts and using solid-state pumping rather than flashlamp pumping has been theoretically supported by Emmett *et al.*¹⁰ and is in the process of experimental demonstration.

I thank my colleagues in the Laser Fusion Program at the Lawrence Livermore National Laboratory who have worked to design, construct and use these systems. In particular, J. L. Emmett has been responsible for the overall programme direction. W. F. Krupke developed many advanced laser concepts, J. B. Trenholme, W. F. Hagen and W. E. Warren developed much of our design methodology, J. T. Hunt and D. R. Speck are readying Nova for target experiments, R. O. Godwin and W. W. Simmons designed and managed Nova construction, K. R. Manes and G. J. Suski led the team that built and used Novette, the precursor to Nova, and D. Eimerl and M. A. Summers provided many of the harmonic conversion ideas.

Laboratory production of X-ray lasers

M. H. Key

Laser Division, Science and Engineering Research Council Rutherford Appleton Laboratory, Chilton, Didcot, Oxon OX11 0QX, UK

Laser-produced plasmas seem to be the most promising sources of soft X rays at the high intensities required for laser action. Strong laser amplification has recently been demonstrated at the lowest X-ray energies, suggesting that true soft X-ray lasers will soon be available in the laboratory.

A MAJOR objective in laser research is to develop X-ray lasers¹. Optical lasers revolutionized optical methods because of the high power, collimation, spectral purity and coherence of their beams. Similar, dramatic consequences could be expected if X-ray lasers became widely available.

Many important scientific applications of intense X-ray emission are already being developed using synchrotron radiation sources². These emit incoherent X-rays from circulating bunches of highly energetic (GeV) electrons deflected by the magnetic field in an accelerator storage ring. A pure continuum of frequencies from infrared to X-ray is generated with high average power in subnanosecond pulses at high (100 MHz) frequency. Monochromators are used to select particular frequencies for applications such as diffraction or spectroscopy, and the emission pulses are accumulated over periods from seconds to hours to obtain sufficient signal.

More recently, single-pulse X-ray measurements have become possible using laser-produced plasmas³. Their incoherent emission results from thermal collisions of electrons with ions in a hot plasma produced by focusing a powerful laser pulse on to a solid target. A continuum of frequencies is emitted by free electrons and narrow lines are emitted by electrons bound to ions. The single-pulse spectral brightness is up to 10⁶ times greater than for synchrotron radiation sources as illustrated in Fig. 1.

To produce coherent laser X-rays has proved more difficult. For a constant laser amplification coefficient, the required fluorescent emission per unit volume on the laser transition scales as frequency $\nu^{4.5}$. Hence there is a need for exceptionally intense X-ray sources for X-ray lasers, the most promising of which seem to be laser-produced plasmas. In this context, a recent experiment at the USA Lawrence Livermore National

Fig. 1 Comparison of the absolute spectral brightness of XUV and X-ray sources. (Synchrotron data are from the SERC Synchrotron Radiation Source (SRS) and laser-produced plasma data are compiled for 10^{12} watt Nd glass lasers.)

Laboratory (LLNL) has generated much excitement by convincingly demonstrating strong laser amplification at a wavelength of 20.6 nm (photon energy $h\nu = 60$ eV; where h is Planck's constant) in a laser-produced plasma⁴. This is the most significant recent advance in short-wavelength lasers, the previous limit having been set at 116 nm ($h\nu = 10.7$ eV) in 1972 with the discovery of the Werner band H_2 laser. Although 116 nm has been the limit for laser action, generation of the seventh harmonic of ultraviolet laser light in gases has extended the short wavelength limit for high-power coherent radiation to 30 nm⁵.

It should be emphasized, however, that 60 eV is only an extreme (X) UV photon energy; a true soft X-ray laser will require a further order of magnitude increase in photon energy. However, the significance of the recent progress at LLNL is that it gives more confidence that a new family of XUV lasers based on high temperature laser-produced plasmas can be developed in the XUV/soft X-ray region >60 eV. Here I describe the characteristics of these lasers, explain how they operate, review recent progress and speculate on their future applications.

Background

All lasers have in common the fact that they produce light amplification by stimulated emission of radiation, hence their name. Stimulated emission was first postulated by Einstein as the quantum inverse of absorption. A quantum of electromagnetic wave energy (or photon), whose energy is $h\nu$, can resonantly stimulate the emission of an identical photon by an atomic electron in an excited state if the energy of the excited state E is $h\nu$, greater than that of a lower state. The new photon is coherent with the stimulating photon, that is the electromagnetic waves have the same phase. Stimulated emission amplifies electromagnetic waves and the inverse process of absorption attenuates them.

The only difference between an XUV laser and a more usual visible light laser is that the laser transition is an XUV frequency. Such transitions occur in high temperature plasmas of highly charged ions and electrons. The reason can be seen in Bohr's elementary model of a hydrogen-like ion illustrated in Fig. 2. The positive nucleus, with one orbiting electron, has a system of energy levels in which the transition energies are

$$h\nu = Z^2 h\nu_H \quad (1)$$

where Z is the charge number of the nucleus and $h\nu_H$ is the transition energy in a hydrogen atom ($Z = 1$).

For example, the Balmer α transition illustrated in Fig. 2 emits XUV photons ($h\nu \sim 68$ eV) when $Z = 6$. The hydrogen-like ion is produced by removing five electrons from a carbon atom leaving a positive nucleus with a single electron, which is isoelectronic (having the same number of electrons) as a hydrogen

Fig. 2 Energy levels of a hydrogen-like ion of nuclear charge $+Ze$ showing the location of the thermal limit when population inversion is obtained between $n = 2$ and $n = 3$.

atom. Such isoelectronic scaling to higher Z shifts the emitted frequency towards the X-ray region.

Production of highly charged ions in plasmas is described by a well-known equation due to Saha and requires high temperatures such that the energy kT in collisions between electrons and ions is an approximately constant fraction f of the ionization energy $Z^2 E_H$

$$kT = fZ^2 E_H \quad (2)$$

The net amplification coefficient resulting from the balance between absorption and stimulated emission on any atomic transitions can be expressed as

$$G = (n_2 - n_1(g_2/g_1))(\lambda^2/8\pi)(A_{21}/\Delta\nu) \quad (3)$$

where n_1 and n_2 are number densities of the lower and upper states of degeneracy g_1 and g_2 , respectively, and A_{21} is the Einstein A coefficient or probability per unit time of a spontaneous transition from the upper to lower state of wavelength λ .

The spectral width $\Delta\nu$ of the transition due to the Doppler shift arising from the thermal velocity of the ions scales as

$$\Delta\nu/\nu \propto (kT)^{1/2} \text{ implying } \Delta\nu \propto \nu^{3/2} \quad (4)$$

There is also a fundamental frequency scaling of the Einstein A coefficient in an isoelectronic sequence

$$A_{21} \propto \nu^2 \propto \lambda^{-2} \quad (5)$$

Amplification (that is, negative absorption) is obtained with population inversion (excess of excited states), that is,

$$n_1(g_2/g_1) < n_2 \quad (6)$$

Equations (3) and (5) show that to sustain a given amplification requires a minimum density of excited states

$$n_2 \propto \Delta\nu \quad (7)$$

The spontaneous fluorescent emission from these excited states has a power per unit volume,

$$p = n_2 A_{21} h\nu \quad (8)$$

and it follows from equations (4) to (8) that

$$p \propto \nu^3 \Delta\nu \propto \nu^{9/2} \quad (9)$$

and it is this $\nu^{9/2}$ scaling of the fluorescent power that makes it very difficult to achieve laser action at high frequencies.

Another major problem is to find methods of creating population inversion when nature tends to create thermal equilibrium in which the well-known Boltzmann relations apply, giving no amplification at any temperature, that is

$$n_2(g_1/g_2) = \exp(-h\nu/kT)n_1 \quad (10)$$

Thermal equilibrium is a consequence of thermodynamic detailed balance in which each transition inducing process is balanced by its inverse process, for example

here collisional ionizations are balanced with three-body recombination. Collisional processes are always balanced by their inverse and therefore in the limit of high plasma density, where collisions are dominant, thermal equilibrium level populations prevail. But spontaneous radiative transitions are most rapid across large energy gaps ($A_{21} \propto \nu^2 \propto Z^4$), whereas for collision induced transitions (of rate $K_{21}n_i n_e$, where n_e and n_i are the number densities of electrons and ions) the opposite is true, with the rate coefficient K_{21} scaling⁶ as

$$K_{21} \propto \nu^{-1} kT^{-1/2} \propto \nu^{-3/2} \propto Z^{-3} \quad (12)$$

The result is that we can identify, in a plasma of lower density, a 'thermal limit' as illustrated in Fig. 2. Above the limit, where energy levels are closely spaced, collisions dominate and below the limit radiative rates are greater than collisional rates. Radiative processes are not in detailed balance unless spontaneously emitted photons are reabsorbed by the plasma. This will not occur unless the plasma volume is large. Thus levels below the thermal limit need not be in thermal equilibrium and, with suitable tricks, population inversion can be created, for example, between levels of principal quantum number $n = 3$ and $n = 2$ in Fig. 2.

In isoelectronic scaling of laser mechanisms to shorter wavelengths it is generally necessary to preserve the balance between radiative and collisional processes so that the thermal limit remains at the same principal quantum number. From the preceding discussion it follows that the temperature $kT \propto Z^2$ and the particle number density $N \propto Z^7$ requiring plasmas of progressively higher temperature and density for lasers of higher frequency.

XUV laser characteristics

The new family of XUV lasers will probably be amplified spontaneous emission (ASE) lasers using single or double transit amplification of spontaneous emission in a long thin volume of laser medium as illustrated in Fig. 3. They are unlikely to have the usual two mirror laser resonator because of the combined problems of short duration of amplification, mirror damage, difficulty of output coupling and criticality of alignment. Here I outline the performance characteristics of such lasers.

The single transit amplification is $\exp(GL)$, where G is the amplification coefficient and L the length. The ASE laser requires a huge single transit amplification to reach the saturation condition where stimulated emission becomes the dominant process. Any plasma-based laser would require $GL \geq 14$, that is, $\exp(GL) \geq 10^6$.

The angular divergence of the laser beam is simply the width to length ratio w/L of the gain medium for a single transit (or the potentially much smaller width to overall length ratio w/L_0 for a double transit with a single mirror), as shown in Fig. 3 and will typically be 10^{-3} – 10^{-2} rad. Further simple atomic physics and plasma physics arguments show that the saturated output power of the laser depends mainly on the frequency and is proportional to the beam area. Assuming a beam area of 10^{-4} cm², typical of the cross-sectional area of the plasma (Fig. 3c) the output power is in the megawatt range

$$P = (h\nu/100 \text{ eV})^{4.5} \text{ MW} \quad (13)$$

The duration of the output pulse depends on the laser mechanisms discussed below and will probably be in the range 50 ps to 1 ns for the new family of ASE lasers.

The fluorescent spectral line width of the laser is usually determined by Doppler broadening giving $\Delta\nu/\nu \sim 10^{-4}$, but laser spectral narrowing further reduces the line width in the laser beam by a factor of ~ 4 . The spectral brightness for the previously discussed parameters is plotted in Fig. 1, showing the dramatic increase relative to even laser produced plasma sources.

Fig. 3 Schematic single-pass (a) and double-pass (b) ASE lasers. c, Schematic model of plasma production by a laser beam focused on to a line.

Emission from an ASE laser is coherent in time only for a period of the order of the inverse spectral bandwidth $\Delta\nu^{-1}$ which from the earlier discussion means $\sim 4 \times 10^4$ cycles of the electromagnetic wave. The spatial coherence across the wavefront is determined by the rather large number ($n = w^2/L\lambda$) of transverse modes excited within the laser beam angle w/L . Transverse spatial coherence is restricted therefore to regions of dimensions of about $1/n$ (typically $1/50$) of the beam diameter. The use of a single mirror to double pass the laser medium offers improvements in spatial coherence through reducing the number of transverse modes.

Experiments and laser schemes

Proving population inversion and amplification. High-power pulsed lasers focused on to solid targets produce small hot expanding plasmas with dimensions 0.1 – 0.2 mm³. The existence of population inversion on XUV transitions was first determined and quantified in such plasmas from the ratio of intensities of spectral lines originating from the potential laser levels (for example, in Fig. 2 the population ratio n_3/n_2 is given by the intensity ratio I_{31}/I_{21} and the absolute intensity I_{31} gives the absolute number density of excited states n_3). Measurements with resolution in space and time were developed for greater accuracy⁹.

Demonstration of population inversion did not prove the presence of net amplification because of the possibility of competing absorption processes such as the photoionization of other ions in the plasmas. In the next phase of experiments direct evidence of amplification was sought using elongated plasmas produced most often in a line focus of length $L = 1$ or 2 mm (this was limited by the available laser power) as illustrated in Fig. 3(c). GL values were measured from the ratio $R(L)$ of spectral line intensities for the laser transition along the axis and transverse to the axis of the plasma. This ratio is theoretically $(\exp(GL) - 1)/GL$ ¹⁰. Earlier experiments were generally not very accurate because GL values were small.

A few very recent experiments have used much longer line foci with $L = 1$ – 2 cm, and new time-resolving XUV spectrometers. With larger GL , variation of the length L between, say L_1 and L_2 allows a measurement of the ratio $I(L_1)/I(L_2)$ which is theoretically $(1 - \exp(GL_1))/(1 - \exp(GL_2))$. Direct evidence of exponential amplification has been obtained in this way. In particular the recent experiments at the LLNL showed GL values ≤ 6.5 (ref. 4).

3p–3s transitions in neon-like ions. The LLNL experiment used an idea which is derived from the mechanism of the familiar argon ion laser and was first suggested in the USSR¹¹. Other researchers followed up the concept^{12,13}, but most effort was confined to the USSR¹⁴ until a few years ago when, as part of

Fig. 4 Energy-level structure of Se^{24+} , after D. L. L. Matthews (personal communication).

a major campaign to test XUV laser options, the LLNL team began serious theoretical studies and experimental preparation for large-scale experiments using the two most powerful laser beams in the world from their new neodymium glass laser Novette.

The energy levels of the neon-like ions are illustrated in Fig. 4; the laser relies upon the fact that the ion has a closed shell of 2p electrons from which excitation by collision with plasma electrons populates the 3p states (as well as 3s and 3d states). There is no quantum mechanically allowed radiative decay from 3p to 2p, but there are strongly allowed transitions from 3p to 3s and 3s to 2p. If the thermal limit lies above the 3s level, then 3s to 2p radiative decay to the ground state reduces the 3s population and creates 3p to 3s population inversion.

The neon-like ion of selenium (Se^{24+}) has 3p to 3s transition energies of ~ 60 eV and was chosen for the LLNL experiments. A very thin (75 nm) layer of selenium was used to avoid reabsorption of 3s to 2p resonance radiation. The final important choice was to use a thin polymer film (50 nm) to support the selenium layer so that, when the target was irradiated with a 450 ps pulse at $5 \times 10^{13} \text{ W cm}^{-2}$, the whole target thickness was uniformly heated producing the Se^{24+} ions at a temperature of $\sim 5 \times 10^6$ K and causing an explosive expansion to a fairly uniform lower density (10^{21} electrons cm^{-3} or $3 \times 10^{-3} \text{ g cm}^{-3}$), at which maximum amplification occurred. The uniform density is vital to reduce refraction of the XUV laser beam as it travels along the 200 nm thick expanded layer of selenium plasma. Detailed calculations¹⁵ suggested amplification coefficients as high as $G = 10 \text{ cm}^{-1}$.

The two large (50 cm) beams of the neodymium glass laser were focused to a 12 mm $\times$ 200 μm line focus allowing up to 2 cm length to be irradiated. Sophisticated time resolving XUV spectrometers viewed the emission axially and transversely and Fig. 5 shows the clinching results. Two of the 3p to 3s lines at 20.6 and 21.0 nm were amplified by up to 500 times along the axis, indicating $G = 5.5 \text{ cm}^{-1}$. The output power was $> 100 \text{ W}$ with a divergence of 10^{-2} rad in a 300 ps pulse. A thermal source would need a temperature of $> 400,000,000 \text{ K}$ for this brightness. Despite the extreme brightness this is still only $\sim 1/3,000$ of the saturated output power which could be obtained with a modest twofold increase in GL . The importance of this result is considerable because it is the first absolutely incontrovertible evidence of high XUV gain. Limited isoelectronic scaling possibilities were also shown in the LLNL work with evidence of amplification in neon-like Yttrium at shorter wavelengths $\sim 15 \text{ nm}$.

Recombination. Population inversions are readily created in rapidly recombining plasmas, though this is not a mechanism

Fig. 5 Exponentially increasing output as a function of length demonstrating single-pass laser amplification of spontaneous emission in the Se^{24+} laser beam (redrawn from ref. 4). Solid circles, 209 Å; open circles, 206 Å; $-g = 5 \text{ cm}^{-1}$.

in any common type of laser. The idea, again Russian in origin¹⁶, dates from 1965 but isoelectronic scaling to the XUV was considered in the United States and the United Kingdom in the early 1970s (refs 12, 17, 18). Recombination from a plasma of bare nuclei to form hydrogenic ions, at densities such that the thermal limit is at $n=3$ or higher, can result in inversion of population between $n=3$ and 2, because of rapid radiative decay depopulating the $n=2$ level. This occurs only if the ground state has an anomalously low population, a situation which can be produced by sufficiently rapid cooling such that the relatively slow process of recombination to the ground state lags behind the fast collisional processes across the small energy gaps populating levels above $n=2$. Fortunately, such rapid cooling is produced almost automatically when a laser-produced plasma expands adiabatically into a vacuum from an irradiated target⁸.

Carbon plasmas have been extensively studied. Early evidence showed population inversion on the 18.2 nm $n=3 \rightarrow n=2$ transition at low densities^{8,9}. Subsequent attempts to produce laser action used cylindrical expansion from 1 to 2 mm long laser-heated carbon fibres. The fibre size was restricted to a few microns in diameter so that the mass of the expanding plasma was small enough to avoid reabsorption of resonance radiation on the 2 to 1 transition. The material of the fibre is heated initially to $kT = 500 \text{ eV}$, at a density $n_e = 10^{21} \text{ cm}^{-3}$. Heating occurs during a 200 ps laser pulse through absorption of between 2 and 20 Joules per cm length of the fibre. Rapid expansion and cooling in the following nanosecond reduces the density to 10^{19} cm^{-3} and the temperature to 20 eV. Recombination into the ground state is minimal. Detailed calculations indicate amplification coefficients from 1 to 5 cm^{-1} of duration $< 1 \text{ ns}$ ¹⁹. The lower amplification is produced paradoxically by higher absorbed energy in a non-critical mode of operation involving total burn through of the fibre. High amplification is obtained with lower mass plasmas produced by partial burn through of the fibre, but demands very precise conditions which are difficult to produce uniformly along by the length.

Experiments have shown evidence of GL up to 4, deduced from axial to transverse intensity ratios, but with poor reproducibility in the high gain mode¹⁰. Experiments in the stable low-gain mode have so far had insufficient plasma length for direct measurement of amplification ($< 2 \text{ mm}$) but have shown good agreement between measurements of the plasma hydrodynamic characteristics and computer modelling¹⁹.

A rather different approach to this kind of laser has been used in other experiments²⁰. Plasma expanding from a carbon target irradiated by a 500 J, 10 GW pulse from a CO_2 laser has been confined to a narrow 1 mm diameter cylinder by an axial magnetic field and rapid cooling has been caused by thermal radiation. Evidence from axial to transverse intensity ratios suggests GL values of the order of 6. Variation of the plasma length is not possible and the feasibility of making a useful laser is difficult to determine. An amplification coefficient of 3 cm^{-1} has also been reported for thin polymer film targets similar to those used in the Se^{24+} laser and radiation cooling from the Se is thought to compensate for the reduced adiabatic cooling of a planar expansion²¹.

Recombination of helium-like (2-electron) ions to the lithium-like (3-electron) configuration is more complex to analyse but is the basis of an almost accidentally discovered mechanism for XUV laser action at 11 nm which has shown quite significant amplification ($G \sim 3 \text{ cm}^{-1}$)^{22,23}. The best results were obtained using 3 GW, 20 ns Nd glass laser pulses and an 8 mm line focus on solid aluminium targets. The laser transition is the 5f-to-3d transition of lithium-like Al^{10+} . The GL value has been determined from the intensity ratio for different plasma lengths as discussed earlier. Measurements have also included time-resolved spectroscopy showing the duration of the gain to be a few ns. Isoelectronic scaling has been demonstrated in similar experiments with magnesium. There are problems however with competing absorption processes which are not well understood. The recombination lasers have amplification coefficient comparable to the 3p-3s lasers and are more attractive for scaling to short wavelength because they use transitions with a change of principal quantum number with strong Z^2 scaling of the transition energy in isoelectronic sequences. They suffer less from refraction because the plasma density is much lower (10^{19} cm^{-3} compared with 10^{21} cm^{-3}) allowing longer plasmas and larger GL values.

Resonant photopumping. Selective excitation by photons is used in many optically pumped lasers and the method can in principle be extended into the XUV as first suggested by Russian authors in 1975 (ref. 24) and elaborated on in subsequent more detailed studies^{25,26}. Current thinking centres on using intense resonance line emission from one species of ion in a hot laser-produced plasma, with a brightness at the line centre corresponding to a black body with $kT_H \sim 200 \text{ eV}$, to resonantly excite another ion species in an adjacent plasma, for example, the $1s^2$ - $1s2p$ resonance line of Na^{9+} at 1.1 nm is absorbed by the $1s^2$ - $1s4p$ transition of Ne^{8+} . If the second plasma has a low temperature, $kT_e \ll kT_H$, and a density such that the thermal limit is above the laser levels, the $n=4$ level may be populated to produce population inversions, such as in the above example for the $4 \rightarrow 2$ transition at 5.8 nm.

Predicted amplification is as high as $G = 100 \text{ cm}^{-1}$ (ref. 26) and potential laser wavelength can be quite short as in the example given. Many such resonances have been identified in H, He, Li and F-like ions²⁵ but as yet there has been no success in demonstrating gain experimentally. But experimental work is at an early stage and the approach has considerable potential. **Other approaches.** The free electron laser (FEL) mechanism in which coherent radiation is produced by deflection of a relativistic electron beam in a periodic magnetic field²⁷ is in theory scalable to any wavelength. But in practice, FEL devices have only been used to generate far infrared, infrared and visible emission, with progressively more difficult problems arising for operation at shorter wavelengths because of a $\lambda^{3/2}$ scaling of the amplification coefficient. It has been argued, however, that operation in the vacuum UV and XUV down to 50 nm might be achieved with magnetic wigglers²⁸ and that even X-ray operation at 0.5 nm could be contemplated with an electromagnetic wave as the 'optical wiggler'²⁹. Major and costly technical problems remain to be solved, including providing both an XUV resonator and a suitable storage ring or Linac of exceptionally high current, low electron-beam divergence and small electron-energy spread. The result could be a frequency tunable laser of high average power in a continuous train of pulses similar to a synchrotron radiation source. (Low power coherent radiation can be obtained from any source by frequency and angle selection and in the XUV synchrotron radiation sources equipped with undulators have been used for this purpose.)

Sudden transfer of stored excitation from long-lived to short-lived states can avoid the need for high fluorescent power and schemes based on charge exchange collisions³⁰ and laser excitation of metastable states^{31,32} are of interest. X-ray laser action at a photon energy of $\sim 1 \text{ keV}$ is reported to have been obtained using a thermonuclear explosion as the pumping source³³. No details of this work have been published, though it may be surmised that the mechanism would involve photon pumping.

The device is clearly not a laboratory laser and its potential applications are in the area of the United States' 'Star Wars' programme.

Future applications of XUV lasers

If, as expected, laboratory XUV lasers are developed successfully in the next few years they will offer powerful, MW to GW single pulses at photon energies (or wavelengths) from $\sim 50 \text{ eV}$ (25 nm) to perhaps 500 eV (2.5 nm). These lasers will only be available at major laboratories where there are exceptionally powerful optical frequency lasers to create the plasmas. So the likely applications will be scientific rather than technological, with powerful XUV lasers complementing other sources, notably synchrotron radiation and thermal X-rays from laser-produced plasmas. The XUV lasers will be used to best effect where time resolution, intensity, spectral purity and coherence are important. Speculation on future applications is likely to be inaccurate since unforeseen developments are usually most significant. The most probable initial applications will be extrapolations of current lines of research:

Soft X-ray microscopy in biology. Recent work with single-pulse soft X-ray emission from laser-produced plasmas has demonstrated high-resolution (50 nm) images of living cells using contact radiography on soft X-ray resists³. A laser source offers the possibility of holographic imaging with better resolution and three-dimensional information, with important implications for progress in biology.

Diffraction from crystals. Analysis of molecular structures from single crystal Laue diffraction is fundamental to biophysics², but suffers from the lack of any information on the phase of the diffraction peaks. A coherent laser source could, by holographic methods, give extra information, leading to unambiguous structure determination. The problem is that wavelengths an order of magnitude less than those envisaged here are needed to resolve the molecular structures, so although some low resolution work of this kind could be contemplated, the major prizes would remain inaccessible. Single-pulse diffraction measurements on transient phenomena³ would be possible, for example, thermal and chemical transformations in thin films and surfaces—but only on systems where crystal structures were larger than the wavelength.

Material processing. Research into holographic replication of submicron patterns in lithography for application to microelectronics, integrated optics or diffraction grating device fabrication could achieve still smaller scale using powerful XUV laser sources.

Atomic physics. Sub-nanosecond selective excitation or ionization of atomic or ionic beams with an XUV laser would open up new possibilities in the high-resolution spectroscopic study of atoms, ions and molecules and would be particularly appropriate for XUV lasers in the low-energy region ($h\nu \leq 50 \text{ eV}$) with the high laser power being important for adequate single-pulse yields and the monochromaticity for high spectral resolution.

Laser physics and nonlinear optics. There is considerable interest in improving the characteristics of the new lasers, developing resonators, schemes for shorter and more powerful pulse generation (perhaps by injecting harmonically generated picosecond pulses into plasma amplifiers) and exploring nonlinear optical effects for the first time at XUV frequencies.

Compact, easy to operate, reliable and self-contained, the VSLs are as versatile as they are affordable. The VSL-337 is a pulsed UV nitrogen laser—or, with one of three available dye laser modules, a tunable visible laser. The VSL-DYE is a single integrated unit, only 12" x 5" x 2", containing both a nitrogen laser and a grating-tunable dye laser module. With a VSL, there are no flowing gases, no tedious aligning procedures—just an intense, pulsed, monochromatic source that allows you to concentrate on your application, not the apparatus.

Use a VSL for time-resolved fluorescence, phosphorescence, fluorescence microscopy, remote excitation, cell stimulation and surgery, PMT calibration, teaching, laser spectroscopy...

The Affordable Advantage

Very Small Lasers at half the price you would expect to pay

- **UV Source**
40kW peak power at 337nm, 3 nanosecond pulse width.
- **Visible Source**
5kW peak power, tunable from 360–950nm.
- **Narrow Bandwidth**
Down to 0.1 Å with the grazing incidence dye module.
- **Portable**
Operates in the field with 12V battery pack.
- **Sealed Plasma Module**
All components with finite lifetimes integrated in a unique replaceable cartridge.
- **Easy to Use**
Plug it in, turn it on. No special skills needed.
- **Focusable**
Entire laser pulse easily focusable to a few microns.
- **Ideal Teaching Tool**
Call for free booklet of experiments.

Lasers, nonlinear optics and optical computers

S. D. Smith

Department of Physics, Heriot-Watt University, Edinburgh EH14 4AS, UK

Devices whose optical properties change with light intensity have opened the path towards the optical computer. Optical switches and signals can now undertake all binary logic operations and complete optical digital circuits have been constructed.

FROM the earliest days of the laser, the large intensities available in laser beams permitted irradiances of the order of MW cm^{-2} incident on material by simple focusing. With such fluxes the amplitude of the oscillating electric field, E , readily becomes comparable to interatomic fields such that the optical properties of the medium vary with the passage of the wave. The polarization, P , induced by the radiation in the simplest case (of a single monochromatic wave propagating through a crystal of high symmetry) has the form

$$P = \chi^{(1)}E + \chi^{(2)}E^2 + \chi^{(3)}E^3 \dots \quad (1)$$

The susceptibilities $\chi^{(1)}$, $\chi^{(2)}$, $\chi^{(3)}$... are related to the optical properties of the medium: as examples, the linear optical properties are related to $\chi^{(1)}$, the second harmonic generation is determined by the magnitude of $\chi^{(2)}$ and the intensity dependence of the refractive index is related to $\chi^{(3)}$. The science of nonlinear optics developed with the observation of second harmonic generation by Franken *et al.*¹ in 1961 and the theoretical prediction of a series of nonlinear effects by Bloembergen² and co-workers.

The large powers required in the early work made it seem unlikely that digital optical computing, using optical circuitry with nonlinear optical circuit elements, would ever be practical. It was nearly 20 years before the experimental discovery that a 30-mW continuous wave (CW) laser beam could be significantly self-defocused in a narrow gap semiconductor produced the surprising conclusion that third order nonlinearities ($\chi^{(3)}$) could have a value of the order of 10^9 times larger than the nonlinearities envisaged by Franken and Bloembergen^{1,2}.

To understand the significance of this giant nonlinearity to a possible future of optical computing, consider the physics of computation (see ref. 3). Information is essentially stored as energy and switching a device from logic 0 level to logic 1 level requires a definite switching energy. This energy must be greater than the thermal energy of the device kT (and will usually be several hundred times kT) and scales as the size of the device. There will usually also be a trade-off between speed and power. A further absolute requirement for electronic or optical logic is the necessity of restoring a logic level after each switching action so that errors resulting from imperfect devices and signals do not accumulate. Restoring logic must have power gain and this power is normally drawn from a power supply independent of the signal channel. (The requirement of power gain is obviously necessary, that is, one switching device must be capable of

driving at least the next in the series so that a circuit containing multiple elements can be constructed.) These considerations appear to be applicable to all systems of signal processing and computing.

The response of semiconductor micro-electronics to the high data rate requirements of digital signal processing and computing has been to increase switching speeds and further miniaturize components in the form of very large-scale integration (VLSI). Transistors made from gallium arsenide have been reported with effective switching times as fast as 12 ps. However, this will not necessarily solve the problem of coping with high data rate as the processing time in conventional computers is many times the logic switching time because of the necessity of transferring information to the next part of the circuit. This involves capacitance time constant limits as pointed out, for example, in ref. 3; VLSI does not solve the time-constant problem because, as the length of a wire shrinks by a factor α and the cross-sectional area of the wire is reduced by a factor α^2 , the capacitance C of the wire decreases by this factor α while the resistance R increases by the same amount. Thus, the time constant RC remains the same and the input charging time remains unaltered independent of scaling.

Turning to the computer as a whole, the standard method of communication in use today connects the logic unit with the memory through an address device. This reduces the number of interconnections but can only address one storage element at a time. This widely used scheme was first suggested by von Neumann but, rather than being given credit for this most practical innovation, he is now rather undeservedly blamed for this so-called "von Neumann bottleneck". The timing problems associated with circulating logic signals around a one-dimensional processor of this type ('clock skew') combine to indicate that future problems in digital computers are likely to be those of communication. This may apply at all levels (architectural, bus and chip) and stems from the use of time multiplex to compensate for the inability of electrical methods to communicate many channels of information in parallel.

Digital optics

Present practice has seen the invasion of electronically based communication by optical methods through the use of optical fibres in long-range telephone lines. The higher carrier frequency used gives potentially higher bandwidth, although electronic

limitations on modulation techniques have restricted our ability to exploit this greater information carrying capacity fully. Currently, long-range transmission made possible by low signal attenuation has been used. The use of optics for processing information has so far been handicapped by the absence of optical circuit elements. The optical methods have promising implications in areas that are currently difficult for existing technologies; these include image processing and recognition, sorting, radar array signal processing, machine vision and artificial intelligence.

During the past 20 years there has also been a body of work often called optical computing practised by optical researchers using linear processing devices, for example, the use of spatial filters and Fourier transform processes in image processing. Ideas include the use of symbolic substitution, residue arithmetic, vector-matrix multiplication and primitive processing experiments using a liquid crystal light valve as a hybrid (that is, optics with electronics) spatial light modulator but not itself capable of all-optical logic action. Most of the reports are theoretical proposals of what might be done (see ref. 4).

The major stumbling block in the development of digital optics has been the absence of nonlinear all-optical circuit elements, preferably capable of fabrication in the form of two-dimensional arrays and of small enough size to have small switching energies and high speeds.

The main purpose of this article is to review the latest state of research in all-optical nonlinear logic switches, amplifiers and memories and to show that, with the experimental realization of the first all-optical circuits, the time is now ripe for the combination of these two previously separate research efforts, optical bistability and linear optical computing techniques.

All-optical circuit elements

Recent progress, which has produced practical all-optical circuit elements, is based on the combination of optical nonlinearity and feedback. This has led to the concept of 'optical bistability' and hence to a whole family of devices based on a common set of physical and mathematical principles. The series of devices includes optical logic gates, bistable memories, amplifiers (sometimes termed optical transistors or transphasors) and power limiters (see ref. 5 for a recent Royal Society, London, conference). The meeting of the International Commission of Optics in Sapporo⁶ presented six papers on optical computing and began the process of introducing the optical bistability community to the optical information processors. The recent Optical Society of America conference⁷ at Lake Tahoe continued this process; a three-element loop processor, using all-optical interactions, was reported, together with experiments on parallel optical computing, using liquid crystal light valves as the nonlinear elements.

A seminal paper on optically bistable devices was that of Szöke *et al.*⁸ who in 1969 proposed that a Fabry-Perot optical resonator containing a saturable absorber as its spacer layer could exhibit two states of transmission for the same input intensity. This simple bistable action was predicted to arise from the existence of a high internal optical field at constructive interference given that sufficient intensity had been incident on the resonator to bleach the absorber. To reach this condition required a greater input intensity than that required to maintain it. By contrast, at low input intensity the non-bleached absorption held the transmission of the device at a low level. In practice this condition is quite hard to achieve experimentally and the experiments described do not in fact show optical bistability. Observation of optical bistability was not made until 1976 when Gibbs *et al.*⁹, using an interferometer containing sodium vapour, observed bistable transmission but deduced that the dominant mechanism was refractive, involving a shift in resonator frequency, rather than absorptive. Nevertheless, effective refractive nonlinearity resulted from a saturation of the atomic absorption. Such a device, although using only milliwatts of power, was relatively large (centimetres in length) and relatively slow (milliseconds) compared with electronic circuit components.

Fig. 1 The dynamics of switching in a Fabry-Perot etalon (see text for explanation of individual diagrams).

In the same year, my colleagues and I made the surprising discovery of giant nonlinear refraction, defined as a function of the intensity, I , from

$$n = n_0 + n_2 I \quad (2)$$

(where the nonlinear refractive index n_2 can be measured in units of cm^2 per kW) present in the narrow bandgap semiconductor InSb. The immediate implication was that a bistable resonator could be made of micrometre dimension and, as the effect was shown to be electronic, would be fast, probably on a nanosecond timescale. A second implication was that one beam could modulate the optical properties of a small slice of semiconductor and affect a second beam, thus making an optical modulator or optical transistor. The details of both the refractive and associated absorptive nonlinearities at milliwatt powers are described in ref. 10 but, retrospectively, the effects could be recognized in the earlier work on the spin-flip Raman laser. Both the device possibilities described above had been practically realized in InSb by 1979 (ref. 11) in which continuous wave laser beams were used, leading to steady-state operation and true optical bistability, as well as the observation of gain in an optical transistor¹².

Simultaneously and independently, optical bistability was reported by Gibbs *et al.*¹³ using pulsed dye laser radiation in the larger gap semiconductor GaAs. Larger absorption and a smaller nonlinearity in this material, however, prevented steady-state operation and this observation was therefore quasi-dynamic and did not permit the demonstration of logic levels or differential amplification.

Origin of giant nonlinearities

The physical explanation of the large nonlinearities in both these semiconductors involves the excitation of electrons to give some degree of saturation or 'blocking'. In the case of InSb, exciton effects are negligible in the conditions of the experiment and a plausible explanation has been given by Miller *et al.*¹⁴ in terms of a 'dynamic Burstein-Moss' shift of the band edge. Physically, a number of electrons ($\sim 10^{15}$ – 10^{16} cm^{-3}) are excited into lower conduction states by the laser photons. The incident intensity I generates an equilibrium number of electrons. Subsequent band filling, following thermalization, modifies the absorption edge and by application of the Kramers-Kronig relationship causes a change in refractive index,

$$\Delta n = \frac{\hbar c}{\pi} \int_0^\infty \frac{\Delta \alpha(\hbar \omega')}{(\hbar \omega')^2 - (\hbar \omega)^2} d(\hbar \omega') \quad (3)$$

Fig. 2 **A**, Experimental observations of a family of characteristics of an interference filter bistable device illuminated by the argon ion laser line of wavelength 514 nm, obtained by changing the initial detuning from resonance of the etalon. The family of curves *a-c* shows the characteristics obtained for different values of the initial detuning parameter $\Delta\lambda$ set by the angle of incidence. If the initial condition is close to resonance, power limiting action is obtained (*a*) as the transmittance can only fall as intensity rises. As $\Delta\lambda$ is increased, curve *b* begins to kink, showing a greater change in output than for an incremental change in input, and thus exhibiting differential gain. This is responsible for optical transistor or transphaser action. Further increase of $\Delta\lambda$ leads to bistable loops of varying width (*c*). **B**, Experimental observation of optical bistability in the interference filter illuminated by light of wavelength 528 nm. The stability of the system is sufficient to allow operation to within $\sim 4\%$ of the power required to switch

where $\alpha(\hbar\omega')$ is the interband absorption coefficient at photon energy $\hbar\omega'$. With $\Delta n/\Delta I \approx n_2$ we can obtain an analytical expression for n_2 . This calculation gives a good description of the resonant refractive nonlinearity in InSb, InAs and CdHgTe.

Device physics

The simplest configuration which provides optical feedback is a simple Fabry-Perot etalon containing a nonlinear refractive material (Fig. 1a). Its optical thickness is given by

$$nL = (n_0 + n_2 I_c) L \quad (4)$$

(where L is the thickness of the material) and this changes with the internal intensity I_c . Consider now the transmission of such an interferometer as a function of wavelength (Fig. 1b): if we start in an initial condition where the illuminating laser wavelength is detuned from maximum transmission by a wavelength increment $\Delta\lambda$ (Fig. 1b), we see from Fig. 1c that the relation between output and input would give rise to, in the case of a linear device, a straight line of low slope: if the device were tuned to resonance and there were no absorption loss, output would be related to input by a line at 45° . If we now increase the intensity from the initial condition, the nonlinear resonator tends towards resonance as its optical thickness changes with intensity. This gives rise to a nonlinear relation between output and input. However, as we approach resonance, the internal field circulating within the resonator itself builds up according to

$$I_c = I_i T(\lambda) (1 + R) / (1 - R) \quad (5)$$

where I_i is the incident intensity, $T(\lambda)$ is the transmission as a function of wavelength (as in Fig. 1b) and R is the (constant) reflectivity of the resonator mirrors. Thus, at resonance the internal intensity is at its maximum where $T = 1$ and is amplified by the term $(1 + R)/(1 - R)$. This gives rise to positive feedback. As resonance is approached, the internal field builds up and

the rate of approach to resonance depends on the change in optical thickness which itself depends on the magnitude of the internal field. The rate of approach to resonance thus speeds up. This can be readily expressed through the expression

$$\frac{d(\Delta\lambda)}{dI_i} = T(\lambda) / \left(\frac{T_{\max}}{2n_2 L} - I_i \frac{dT}{d\lambda} \right) \quad (6)$$

Figure 1d shows a plot of the rate of approach to resonance as a function of either incident intensity I_i (or as a function of time if we assume a linear ramp of I_i against time; Fig. 1e). As I_i increases, $dT/d\lambda$ also varies, the denominator of equation (6) tends to zero and the rate of approach to resonance becomes infinite, leading to rapid switching. This gives a physical feel for the dynamics of the switching process and leads to optical bistability (Fig. 1c), that is, two values of the transmission for one of the intensity. Two features are noteworthy: (1) a large value of finesse (ratio of spacing to half-width of the transmission peaks) makes it easier to obtain bistability; and (2) the form of the characteristic (output versus input) changes with the initial conditions, that is, it depends on $\Delta\lambda$.

Such a set of characteristics is illustrated in Fig. 2, giving a set of experimental results for nonlinear interference filters incorporating ZnSe films as the active layers (curves *a-c*). Thus, by a simple change of initial conditions a whole family of optical devices can be produced.

Figure of merit for optical devices

An analysis of the factors concerned in the design of such optical circuit elements has been given by Miller¹⁵, who shows that the quantity which gives a figure of merit (in terms of nonlinear Fabry-Perot cavity optical switching in the presence of linear absorption, α) is $n_2/\lambda\alpha$. This determines the lowest critical value of input irradiance I_c for a device of given size to obtain bistable switching or nonlinear characteristic:

$$I_c = \frac{\alpha\lambda}{n_2} f(R, \alpha L) \quad (7)$$

The result is physically sensible as the switching power will be lower for a larger nonlinearity n_2 , the shorter the wavelength the smaller will be the refractive change required to effect a change from constructive to destructive interference (that is, $\Delta(nL) = \lambda/2$) and for a smaller absorption (assumed linear in this analysis) the longer the device may be for a given loss. The function f optimizes cavity properties. Values of $n_2 = 0.1 \text{ cm}^2 \text{ kW}^{-1}$ and $\alpha = 10 \text{ cm}^{-1}$ give useful devices of thickness (L) 50–200 μm , bearing in mind that a fractional change $\Delta n/n \sim 10^{-3}$ is usually required.

To obtain favourable values for $n_2/\lambda\alpha$, we make particular use of effects resonant with the energy gap E_G in semiconducting materials. For electronic nonlinearities it can be shown that $n_2 \sim 1/E_G^3$ so that $I_c \sim 1/\lambda^2$. In addition, the considerations made earlier suggest that the smallest possible devices should be constructed. Diffraction limits suggest that the area limit will be $\sim (\lambda/n)^2$ and thus, although the nonlinearity is clearly large at longer wavelengths for small gap materials, the interference conditions and device size favour shorter wavelengths. Analysis of the detail of the frequency dependence of the nonlinearity, together with the attendant unwanted losses, has not so far indicated an optimum wavelength.

Semiconducting compounds have shown promising results: InSb with a typical working wavelength (5.5 μm) corresponding to $1,820 \text{ cm}^{-1}$ is one material for which there are sufficient available laser frequencies to undertake a detailed examination of the frequency and hence resonant behaviour of n_2 and α near the band gap^{5,14}.

GaAs has also been investigated^{5,13} but differs by having a strong exciton feature near the absorption edge. The nonlinearity $n_2 \sim 10^{-3} \text{ cm}^2 \text{ kW}^{-1}$ is quite practicable for devices, but the absorption coefficient in epitaxially grown material is so far giving values of $\alpha \sim 10^4 \text{ cm}^{-1}$. Thus, thicknesses are restricted to a few micrometres and thermal stability poses a problem.

Both the above materials show negative values of n_2 caused by electronic effects. Carrier lifetimes are in the range of tens to hundreds of nanoseconds. The nonlinearities can be 'switched on' more quickly than this time interval by rapidly introducing carriers with relatively intense pulses. The relative figures of merit between GaAs and InSb favour InSb by a factor of 10^5 , which has given InSb the advantage of steady-state operation but the disadvantage of a low operating temperature of 77 K, whereas GaAs has operated at room temperature and at shorter wavelengths. So far there are no reports of true steady-state operation for GaAs material. Other materials, which have been used in purely optical switching devices, are reported in ref. 5.

There is a second useful form of nonlinearity involving thermal shift of the band edge resulting from temperature rise of the bulk of the nonlinear material. This effect also resonates with the band edge and is associated with moderate values of absorption coefficient. The quantity taking the place of n_2 is an effective $n_2 = (dn/dT)\alpha(LL'/\kappa_s)$ where L, L' introduce dimensions of film and substrate thickness and κ_s is the thermal conductivity of the substrate. Interference thin film structures using ZnSe (ref. 16) have given promising results for refractive switching, and bulk ZnSe, CdS and GaAs also show 'optical bistability by increasing absorption' where the thermal shift introduces the required feedback⁵.

Requirements for optical computing

Since our proposition is to undertake logic operation by means of these optical circuit elements, we can define some of the requirements if they are to be put together in the form of optical circuits to construct an optical computer. Requirements are as follows: (1) High contrast. A logic device needs to show a large change between logic 0 and logic 1 levels. (2) Steady-state bias. To make various different logic gates it is necessary to alter controllably optical bias levels. In terms of optical bistability this means that the device can be 'held' indefinitely at any point on the characteristic with a CW laser beam—the 'holding beam'—and implies a degree of thermal stability. Devices based on InSb at 77 K and on ZnSe at 300 K have been the first to show this behaviour. (3) External address. For logic functions it is clearly necessary that separate external signal beams can be combined with the holding beam to switch the device. The switching energy in fact is derived from the holding beam and this switched beam propagates in transmission or reflection as the output beam to the next devices in an optical circuit. (4) The elements must be cascable. This means that the output of one device must be sufficient to switch at least one succeeding device. The ability to set a CW holding beam near to switch point in fact fulfils this condition because the extra increment is then small compared with the change in output even in the presence of loss. As each device has its own 'power supply' (that is, holding beam), logic levels are restored. (5) Fan-out and fan-in. The probable advantages of parallel processing in optical devices emphasize the ability that one device can drive many succeeding devices, probably using free space propagation for address. The summed effect of several elements can readily be focused on one device to achieve fan-in. (6) High gain. Items (4) and (5) demand that the elements show a value of differential gain ratio of change in output to change in input of >1 . (7) Arrays. The technology shall ideally be such that two-dimensional arrays are easily constructed. (8) Power and speed. Low power per device is a necessity and this should preferably be of the order of milliwatts or less; this is aided by fabricating small-area devices. Speed and power will be interchangeable but speed itself will vary with use: for parallel arrays, microseconds will suffice and for one-dimensional circuits, sub-nanosecond or picosecond switching times are desirable.

Experimental results

Figure 3a shows an early result for an InSb resonator operating in transmission. The critical switching power is 20–25 mW incident on a diameter of $\sim 200 \mu\text{m}$. If the device is set up in

Fig. 3 *a*, Transmission characteristic of an InSb etalon illuminated by a steady-state carbon monoxide laser operating at a wavelength of $5 \mu\text{m}$. The laser power is constant at a level slightly below that required to switch. *b*, The change in transmission induced by the absorption of 35 ps long pulses from a Nd:YAG laser ($1.06 \mu\text{m}$) and total energy 5 nJ.

this way with the holding beam adjusted in intensity to be just short of the switch point, the device may be externally addressed. Figure 3b shows the results obtained using a single 35-ps long pulse of 5 nJ energy from a Nd:YAG laser. The arrival of the single pulse is sufficient to trigger the switching and the device remains in the 'on' state. Interrupting the holding beam returns the switch to the 'off' state, and as can be seen the logic levels are extremely stable. The device was further developed to show explicit AND gate operation by dividing the switching pulse with a beam splitter and observing that the switching energy was quite definite so that the device could be set to switch only when both pulses were incident (in addition to the steady-state holding beam) and would not switch with a single pulse. The device is therefore acting as an AND gate and an optical memory.

We may deduce that sufficient free carriers were induced near the surface of the InSb resonator to cause sufficient change in optical thickness to initiate switching within ~ 3 ps. W. Kaiser (personal communication) has shown recently that this nonlinearity can be switched 'on' in <7 ps. Therefore, the probable switching time is limited only by the macroscopic effect of internal field build-up within the resonator. This depends only on the round-trip time for the $210\text{-}\mu\text{m}$ thick etalon and amounts to ~ 8 ps. We may infer that picosecond timescale optical logic has been demonstrated.

First digital optical circuits

With CW steady-state hold, an InSb logic device can be switched with incremental power as little as $3 \mu\text{W}$ (Fig. 3). Thus, the output change of the device operating in reflection (Fig. 4), ~ 4 mW, should be sufficient to switch a succeeding device. A first experiment using two optical switches, A and B, is illustrated in Fig. 4. This first example of an optical logic circuit is equivalent to an XNOR gate.

Thin-film interference structures comprising alternate layers of high- and low-index material deposited on a flat substrate such as float glass are a convenient way of constructing a resonator equivalent to the devices described earlier. If sufficient nonlinearity can be induced in the very thin interference layers the technology has many advantages, particularly that very uniform devices covering many square centimetres can be easily made. Thus, large-area arrays are readily possible. Typical total thicknesses of films for a device with 15 layers are only $\sim 2\text{--}3 \mu\text{m}$.

Fig. 4 The experimental arrangement used in the fabrication of an XNOR gate by the coupling of two InSb logic gates and the characteristics of the individual (*a*, *b*) and coupled (*c*, *d*) gates. Optical switch A is addressed by a holding beam which is reflected from the element and focused on to a second element, B, 500 μm away on the same crystal slice. This second element is held near to switch point by a second holding beam illuminating it from the opposite side. The output of A then acts as the address beam for B and the optical circuit output is observed as the reflection from B (B_{ref}). The figure also depicts the circuit inputs and outputs as the input to A (A_{in}) is steadily increased until a point is reached where its reflected output acting as address on B causes this second gate to switch to a lower state in reflection (*c*), (*d*). B remains in this lower state until A itself switches down in reflection, when B simultaneously switches up in reflection. B remains in the up state as the input to A is further increased until it again switches down when the reflected input from A is high enough. If A were to be held close to switch point and addressed with a pulse, information would be stored in A. If the holding beam on B is at the same time too far from switch point, the information will not be transferred from B. If this holding beam is then programmed to come within the range where B can be switched, the information can be transferred to B and by an appropriate reduction of the holding beam on B the information can be moved from A. The device can therefore be made to act as a shift register. With further holding beams defining optical circuit elements across the crystal, these forms of optical logic become indefinitely extensible.

The heat capacity of pixels of micrometre dimension is low and implies that incident power of ~ 10 mW can cause a temperature rise of 50°C in ~ 1 ns. The important physics lies in the control of heat sinking by means of the conductivity of a relatively massive substrate. Figure 2 shows the very promising results obtained using ZnSe as the active film which has a band gap conveniently resonant with argon ion laser wavelengths at 514 and 528 nm. The important property recently found is that these logic switches are sufficiently stable to permit construction of optical circuits of a similar nature to those already demonstrated with InSb^{5,17}.

Optical computers

I have described the contemporary performance of several optical circuit elements and shown that, in principle, all logic functions familiar in electronics can be reproduced by these nonlinear optical devices. Therefore, it should be possible to construct an all-optical computer.

There exists a considerable body of literature reporting the research of a number of groups on the subject of optical comput-

Fig. 5 *a*, A schematic model of the arrangement used to demonstrate a three-gate optical delay which forms the basis of a loop processor. *b*, The clocking of the individual bias levels to the three gates.

ing⁴. To date this has not included the use of the nonlinear elements discussed here. Nevertheless, the advantages of using optical methods for various computations have been apparent for several years. Historically, most optical computing systems have been of analog type in which information is stored and processed as a continuum of signal levels. There are major drawbacks to such analog systems, including limited flexibility, noise accumulation and input/output device limitations. The advantages of optical binary logic, now in principle possible with the devices described here, may be crucial in progressing optical computing into a new practical technology. One would wish to avoid as many photon-electron or electron-photon conversions as possible. The considerations can be made at several levels, including individual optical logic devices (gates and arrays of devices) as the first level. The second level considers optical communications interconnections and input/output among the logic gates, among arrays and among circuit boards or processors. The third level considers the possibilities of new computer architecture to take advantage of the inherent parallelism of optics.

Thus, one might see the advantages of optical methods in two separate ways: (1) Speed of switching and communication. I have shown that individual optical logic operations can almost certainly be performed on a picosecond timescale. Combining this with the output characteristics of CW mode-locked lasers, it is possible to conceive bit rates approaching frequencies of THz for an exact analogue of electronic digital logic. It is not yet clear that recovery times can be imposed on the optical logic switches at acceptable power levels to ensure continuous operation. The possibility exists of series-to-parallel and parallel-to-series conversion on picosecond timescales. Fast, high bandwidth communication will also be consistently available. Optical methods may defeat clock skew. (2) Parallelism and communication. The logic devices described here are at this time the only ones which have been capable of providing steady-state information holding and cascable operation. They have time constants in the range 100 ns–100 μs . This suggests that the first approach to the use of optics should emphasize the use of parallelism and accept cycle rates similar to existing electronic speeds. The intriguing intellectual challenge is to use the flexibility of optics to provide appropriate interconnections:

Fig. 6 The types of optical computer being proposed use the parallelism of optics by using arrays of elements. The iteration present in the type of problem which could be solved on such a computer is achieved through the use of a loop processor architecture. The individual arrays of elements may have to be flexible in their uses in the processor, identical arrays may be used as input (I), clock (C), gain (G), program (P), dynamic interconnect (DI) and output (O). Each array may require a separate power supply refresh (R).

requirements could be to shift a logic array pattern by one element on each cycle or to achieve a 'perfect shuffle'. Other schemes include a vector-matrix multiplication involving a fan-in from a matrix array to a column followed by rotation of this column between output and input for successive cycles.

In my laboratory a number of optical-computer architectural components have been designed including memory units, clocks, a programmable processing stage and a simple full adder using simultaneously the transmission and reflection from an optical gate¹⁸. The necessity to store the calculation before communicating to the next element is important in the optical case: propagation at the speed of light otherwise would mean that all elements would be simultaneously addressed (admittedly, avoiding clock skew³). Delays can be readily implemented by suitably programming the holding beams so that the optical bias is only set to receive a signal when the device is clear of other signals. As a first step, consistent with the elements described, this could be achieved electronically making an interesting interface to existing computer technology. At the time of writing, a three-element loop processor with optical bias delay loop clocking has been implemented. Acousto-optic modulators, controlled by a micro-computer, provide both optical bias levels and input data pulses (Fig. 5). In principle, indefinitely extensible optical logic has been demonstrated. A generalized optical computer using these ideas may take the form shown in Fig. 6.

Conclusion

One may conclude that practical optical circuit elements have been demonstrated, that all binary logical operations can be performed and that the first digital optical circuits have been shown to be practical.

At this time the most favourable method of applying optical methods to digital optical computing seems to be the use of digital arrays of gates speaking (in an optical sense) to further arrays of gates with the possibility of fixed or variable-intercom-

munications, fan-out and fan-in using free space propagation as efficient ways of 'optical wiring'. It remains to be shown that holding powers and switching energies are sufficiently small to allow operation with existing lasers and devices. Scaling from present experimental results, one may deduce that, for a visible wavelength device, a single logic element area of $\sim 1 \mu\text{m}^2$ should be practical, which, with a 250-ns switching time, should require 0.2 mW of holding power. Perhaps 10% of this would be absorbed. The 10 W available in the 514-nm argon ion line from a typical commercial laser would allow the operation of 5×10^4 gates assuming perfect optics. This would give the array a rate of information processing equivalent to 2×10^{11} logic operations per second assuming that all the gates are used simultaneously. A similar number of logic operations could be achieved by using small-gap semiconductors in the infrared where the electronic processes would allow faster switching but the packing density and device size would be greater. The optimization of the existing devices and the use of different materials may allow the synthesis of arrays capable of much higher data rates.

Even allowing for imperfections, which would reduce these numbers, the data rates are sufficiently high to encourage the exploration of their use for tasks where conventional one-dimensional sequential digital electronics finds difficulties, such as pattern recognition, artificial intelligence, sorting and specialized computational problems. Equally interesting will be applications such as power limiters, optical noise reduction and laser projectors and displays.

International development programmes

Several collaborating groups are actively involved in research in these areas. The principal effort in Europe is the European Joint Optical Bistability Program, a multinational project on optical logic circuitry and the basic physics of optical bistability involving eight universities and institutes in Britain, Belgium, West Germany, Italy and France. There are a further eight European laboratories associated with the programme. The research support scheme was established in 1984 by the Commission of the European Communities, through its Committee for the European Development of Science and Technology.

In the United States there are two main collaborative groups: The Optical Circuitry Cooperative is currently being established by the University of Arizona, which is involved with over 10 American companies with an interest in optical circuitry. The five-year programme is funded by these companies, the university and a NSF grant. The Pentagon recently announced the formation of a consortium of nine research organizations, including seven universities which will be funded as part of the Strategic Defense Initiative to produce an optical computer.

Japan's Optical Computer Group was formed in 1983 with the purpose of providing the opportunity for its 75 members to exchange information and ideas in the field of optical computing. The group has four to six meetings every year and publishes a newsletter (*Opcom news*) between meetings. The group is associated with the Optics Division of the Japanese Society of Applied Physics with members from Japanese universities and companies.

I thank Dr F. A. P. Tooley for help in preparing this manuscript as well as all members of the Heriot-Watt optical circuits research group and the participating laboratories of the European Joint Optical Bistability project of the Commission of the European Communities.

Laser biology and medicine

V. S. Letokhov

Institute of Spectroscopy and Laser Technology Centre of the USSR Academy of Sciences, Moscow, Podolskii Rayon, Troitzk 142092, USSR

The substantial repertoire of laser radiation—its coherence, range of intensity and frequency, controllability of focal area and of beam length—has been comprehensively explored in the contexts of micro- and macro-diagnostics of cells, biochemical kinetics, therapy and surgery.

TWENTY-FIVE years have passed since the first laser, whose underlying principles were described by Basov, Prokhorov, Townes and Schawlow^{1,2}, was created³. The main applications of lasers were immediately forecast, but the widespread subsequent developments, such as diagnostic, therapeutic and surgical tools in biology and medicine, were not foreseen.

Biomedical laser applications have already been examined in a series of reviews⁴⁻⁸. The present review, timed to coincide with the 25th anniversary of the laser, surveys some recent developments in this field and outlines the new possibilities of laser techniques in disciplines such as photobiology and photo-medicine, concentrating on the main trends in development.

All biomedical laser applications are based on the interaction of laser light with biological substances. Such interaction causes a broad spectrum of effects, so lasers can be used in a wide range of fundamentally different applications (Fig. 1). In the simplest case, low-intensity laser light is absorbed, reflected or reradiated (as fluorescence) by the substance so that no changes occur within it. Such interactions form the basis for diagnostic laser applications in biology and medicine, both for diagnosis at the atomic or molecular level (spectral diagnostics) and at the macroscopic level (such as motion and shape of cells and organs).

Ultraviolet and visible radiation can excite electronic states in many biologically important molecules leading to photochemical transformations at the molecular level. Such processes occurring under the effect of light from incoherent sources are studied by photobiologists and find practical application in photomedicine^{9,10}. The use of laser light in these disciplines gives several benefits, first, it enhances the speed at which molecules are excited, making it possible to probe photobiological reactions on a picosecond timescale¹¹ and second, it excites higher electronic states in the target molecules through multiphoton processes.

High-intensity laser radiation can cause damage to matter through various mechanisms, for example, liquefaction, intensive heating, evaporation and dielectric breakdown. Such processes, rarely observed under the effect of incoherent light sources given their relatively low intensity, now underlie laser material processing. The same physical processes have proved effective in laser-beam surgery.

Fundamental to these diverse applications of laser light is its unique properties: (1) spatial coherence, allowing laser radiation to be focused and introduced into an optical fibre; (2) monochromaticity or temporal coherence, allowing laser spectral analysis and the resonance excitation of certain molecules; (3) high intensity (or temperature), providing a high concentration of light energy in the substance being irradiated, thus giving

rise to multiphoton processes, heating in the substance and other processes; (4) 'compressibility' into ultra-short pulses, allowing the study of very fast (subpicosecond) primary photoprocesses and the excitation of high-energy levels in molecules at a rate exceeding their relaxation rate¹²; (5) tunability in the range from the infrared to the ultraviolet, which permits selective excitation of certain molecular species. Of course a single laser can provide a combination of several of the above properties, although only one or two are essential to each particular application. I consider here the three areas of biomedical laser applications.

Laser diagnostics

Of importance in biology and medicine are microdiagnostics at the atomic and molecular level and macrodiagnostics at the level of cells and organs. Laser techniques are of great value in both cases.

Atomic and molecular diagnostics. Spectral analyses, such as trace-element analysis in studies of metabolism and toxicology, absorption and fluorescence techniques for the analysis of biological molecules, were performed extensively before the laser was devised. However, spectral analysis without the laser enables the detection of at best $\sim 10^{10}$ atoms or molecules of a particular species in a typical sample. Using lasers, ultra-sensitive analysis techniques^{13,14} were developed which make it possible to detect even single atom or molecule¹⁵. Furthermore the high spectral resolution and selectivity of laser spectroscopy techniques frequently allow the atomic content of samples to be determined directly, without resorting to preliminary separation into components and subsequent chemical analysis. (One example is direct resonance ionization detection of traces of aluminium in human blood¹⁶.) This highly sensitive and selective technique is universal in scope and provides a means of classifying the content of elements in various human organs (down to specific cells) and of revealing their role in human metabolism under both normal and pathological conditions.

This task is inseparable from the analysis of the environment (for example, flora and fauna, foodstuffs) for toxic and pathogenic materials, and the determination of pathways by which they enter the human organism. Here, laser-spectroscopy techniques are especially effective^{13,14}. Even the comparatively simple fluorescence analysis method is highly sensitive when used with the laser, in combination with chromatography. For example, the detection sensitivity for aflatoxins¹⁷ was about 10^{-10} g (10^{-12} mol) until the laser technique was developed; laser resonance photoionization of molecules and mass spectrometry increase the detection sensitivity by several orders of magnitude. Thus, for example, a detection sensitivity as high as 10^{-14} g has been reached for tryptophan in water¹⁸.

Fig. 1 Main trends of laser applications in biology and medicine, based on various degrees of laser light interaction with molecules, from diagnostics to destruction.

The absorption and fluorescence spectra of human tissues under normal conditions differ from those under pathological conditions, a phenomenon long used in diagnostics. The use of laser light, which can be easily delivered into the human body and focused on the desired spot, has extended the capabilities of such techniques. For instance, laser-fluorescence bronchoscopy is effective in early lung-cancer localization¹⁹. The technique uses a sensitizer, haematoporphyrin derivative (HpD), which concentrates predominantly in tumour cells. This compound absorbs light in the 400-nm region and fluoresces in the red region, allowing the detection of cancer at an early stage. Recently it has been shown that the fluorescence spectra of normal and atherosclerotic blood-vessel walls differ appreciably²⁰, a phenomenon which may prove valuable in operative diagnosis in blood-vessel surgery, an area of particular importance in view of the prospects for the development of laser blood-vessel surgery (laser angioplasty), discussed below.

Optoacoustic spectroscopy may, in future, be used to localize intraocular malignant melanomas²¹. The technique involves the generation of ultrasound at a spot inside the eye by focused laser radiation and detecting inhomogeneities by monitoring both the generation and propagation of the sound.

The development of fibre optics and the subsequent creation of fibre-optic sensors for biomedical applications²² have extended the capabilities of the laser spectral diagnosis of internal diseases. Such sensors have already been successfully used for fluorometric analysis, but possibilities here extend much further, because optical fibres allows transmission of light to the desired spot inside the human body not only in therapeutic but also in higher, surgical, radiation doses.

Laser radiation can be focused into a small spot of the order of the radiation wavelength, λ , in size. This property is being exploited in a range of techniques for the microspectral analysis of biological objects. For example, focusing an intense laser pulse onto the surface of a biological object can help to evaporate a $\sim 1\text{-}\mu\text{m}^3$ microsample and produce atomic and molecular ion species in the process; mass analysis of these species can provide information on the atomic and molecular composition of the sample²³. This principle underlies the commercial laser micromass analyser (LAMMA) manufactured by Leybold Heraeus.

Using a tunable laser radiation of a lower intensity allows the study of Raman scattering, absorption and fluorescence spectra of small areas of material without its being destroyed. This forms the basis, for example, of the laser microfluorometry of the processes occurring in single cells or organelles in the living state, the spatial resolution is as high as $0.3\text{ }\mu\text{m}$ and temporal resolution, 0.2 ns (ref. 24). Such a technique could be useful in the fluorescence mapping of genes. One possible technique for the direct observation of the primary structure of DNA is by means of a combination of the selective laser ionization of molecular chromophores with ion-field microscopy²⁵. This technique, which I and my colleagues have been working on for 10 years, would enable analysis of genetic information of individuals and early diagnosis of hereditary diseases.

Currently at the development stage are laser techniques for detecting rare radioactive isotopes, based on the isotope-selective detection of single atoms²⁶ and independent of the radioactive decay process itself. Such methods can be used as the basis for isotope analysis *in vivo* of metabolic pathways in an organism using rare isotope tracers of ultra-low radioactivity. In this context, it would be possible to conduct experiments, even at the cellular level, at a harmless radioactive dose.

Lasers can produce powerful ultra-short light pulses with a duration in the range 10^{-9} – 10^{13} s and, recently, in the femto-second range (down to $20\text{ fs} = 2 \times 10^{-14}\text{ s}$) (ref. 27). Picosecond light pulses have found wide applications in the investigation of primary processes involved in photosynthesis, vision and biochemical reactions involving haemoglobin, DNA and other biologically important molecules, which occur after absorption of a photon^{11,28}. This application of lasers has developed into a vast area of research, providing biochemists with direct and

Fig. 2 Scheme of optical and electronic arrangement used to measure Doppler-shifted spectra from human retinal vessels. The basic optical component is a standard fundus camera modified with laser-input optics, internal fixation target and an optical fibre mounted in a scanning ocular (from ref. 32).

reliable information on ultra-fast primary photoprocesses for which only indirect data have been previously available.

Macrodiagnostics. The high monochromaticity and coherence of laser radiation allow measurement of the position, velocity, small displacements and shapes of various components of biological objects, that is, to perform macrodiagnostics for biomedical purposes.

One of the first effective biomedical laser applications was in flow cytometry, where the laser was used to effect the rapid analysis and separation of individual mammalian cells^{29,30} by accurately measuring their optical properties (particularly laser-induced fluorescence characteristics). The cells in suspension exist in a fast-moving, very thin laminar stream which is irradiated by a laser. When a cell of the desired species crosses the laser beam, it begins to fluoresce. The fluorescence triggers a system that diverts the droplet containing the cell. Such laser fluorocytometers are now available commercially; the next step will be to develop a technique for separating male and female cells by the slight differences in their fluorescence spectra resulting from differences between their sets of chromosomes.

Another effective laser application is the measurement of slow fluid flow velocities, particularly blood-flow velocity in vessels. The technique is based on the Doppler shift of the output frequency of a monochromatic laser (usually a He-Ne laser operating at $\lambda = 6,328\text{ Å}$), which occurs as the laser radiation is scattered back from micron-sized particles moving in the blood flow. For example, at a flow of $v = 1\text{ cm s}^{-1}$ the frequency shift, $\Delta\nu$ of the He-Ne laser is $\Delta\nu = V/\lambda = 1.58\text{ kHz}$ and can be detected by monitoring the beat signal on a photodetector receiving both the incident and reflected (back-scattered) radiation. Laser Doppler velocimeters allow for continuous non-invasive blood-flow velocity measurements at the capillary level³¹. As an example, Fig. 2 illustrates schematically the direct measurement of retinal blood-flow velocity in the eye³². The eye is especially convenient for such measurements as its natural optics make it easy to deliver light to the desired microcapillary with an irradiation region diameter of only $100\text{ }\mu\text{m}$. However, the development of fibre optics has made this technique applicable to other blood vessels³³. These fibres enable the measurement of blood-flow velocity profiles with a resolution of 0.1 mm or better, and velocity variations lasting $\sim 0.01\text{ s}$ or less²². By such means it will be possible to measure microcirculatory blood flows with high resolution using an optical fibre brought into contact with the tissue of interest. The development of compact diode lasers should eventually make this technique available for general medical applications. Moreover, the capabilities of the laser-Doppler technique extend much further, for example, it can be used to measure the mobility of bacteria and spermatozoa and to perform electrophoresis of cells and organelles³⁴.

With the advent of lasers, one of the most important pre-laser discoveries in optics, holography³⁵, has become a powerful

Fig. 3 Methods of photochemical modifications of biomolecules. *a*, One-photon excitation and subsequent photochemical reaction (phototherapy of neonatal jaundice by means of photodecomposition of bilirubin). *b*, One-photon excitation of sensitizer molecule, *M*, and transfer of excitation to modifiable molecule or molecules participating in modification photodynamical effect (tumour phototherapy; the oxygen-acceptor of excitation participates in oxidation). *c*, Two-photon excitation of highly lying triplet, T_1 , or singlet, S_1 , states and following photomodification or transfer of excitation to other molecules (nucleic acids in water).

diagnostic method. Using holography it is possible to obtain three-dimensional images of biological objects; their contours can be mapped (holographic topography) and their deformations can be analysed on a real timescale (holographic interferometry). These new possibilities have been influential in many areas of medicine, including orthopaedics, radiology, ophthalmology, urology and otology³⁶.

Femtosecond light pulses are compressed in space (a pulse duration of $50 \text{ fs} = 5 \times 10^{-14} \text{ s}$ corresponds to a pulse length of $15 \mu\text{m}$ in air). Thus, the possibility arises of direct optical measurement of small distances on the principle of a pulsed optical radar. This technique is applicable to investigations with micrometre-scale spatial resolution into biological systems such as the interior of the eye or skin³⁷. When combined with fibre optics, the technique may have interesting applications in studying human internal organs.

Molecular photobiology and photomedicine

Within this vast area lie those laser applications which make use of photochemical processes resulting from photo-excitation of biological molecules (Fig. 1). To outline what laser light can provide in this area, I consider general schemes of molecular photoexcitation following adsorption of one or more photons (Fig. 3). When being acted on by low-intensity light, a molecule can absorb no more than one photon because the excitation rate $W_{\text{exc}} = \sigma I$ is much lower than the relaxation rate $1/\tau_{\text{rel}}$ of the excited molecule (σ is the excitation cross-section, I the radiation intensity in photons/cm² s, and τ_{rel} the excitation-relaxation time). The excited molecule either takes part in a chemical reaction (Fig. 3*a*) or transfers its excitation to another molecule participating in a chemical transformation (Fig. 3*b*). However, under the effect of short laser pulses of intensity I is so high that $W_{\text{exc}} \approx 1/\tau_{\text{rel}}$, the molecule can absorb a second photon either from a triplet state or from an excited singlet state (Fig. 3*c*). The excited molecule again can suffer both a photochemical transformation and transfer excitation to another photochemically active molecule. The first two schemes form the basis for linear, one-photon photobiology⁹, while the third (and, perhaps, schemes involving the participation of more than two photons) underlies nonlinear, multiphoton photobiology^{12,38}. These two approaches impose different requirements on the laser intensity.

One-photon excitation. One-photon photobiochemical processes, such as phototherapy of neonatal jaundice (hyperbilirubinaemia)³⁹ (Fig. 3*a*) phototherapy and photochemotherapy of various skin diseases (Fig. 3*a, b*)⁴⁰ and photochemotherapy of cancer with the aid of the haematoporphyrin derivative HpD⁴¹ are well known in photobiology⁹.

The last case is a classical example of phototherapy following the scheme of Fig. 3*b*. The HpD molecule tends to accumulate

predominantly in malignant tissues. At the same time, HpD is readily activated with visible light and, once excited, transfers its excitation through a triplet state to the oxygen molecules present in the tissues. The oxygen molecules excited to a singlet state ($^1\text{O}_2$) are chemically active and cytotoxic. The entire mechanism is termed the photodynamic effect⁴².

The light intensities required for all photoprocesses are not very high ($< 1 \text{ W cm}^{-2}$), and so they can be performed under the effect of light from incoherent sources. Nevertheless, the use of laser light here is extremely useful for the following reasons. First, laser radiation is easily delivered to the internal organs through optical fibres without significant loss of intensity. This considerably extends the capabilities of phototherapy, allowing one, in principle, to change from the treatment of external organs to that of any internal organ⁴.

Second, the high intensity of laser radiation ensures a high rate of photochemical processes, irrespective of the excitation of high-lying electronic states. This laser light provides a therapeutic dose over a briefer time span than is possible with radiation from conventional sources. It is for this reason that lasers have given a fresh impetus to the development and improvement of established cancer photochemotherapy techniques using ultraviolet and visible radiation⁴¹.

Third, the necessary irradiation dose can be provided by a single short pulse, which is of particular use in those cases where the effect of light on subsequent secondary chemical reactions must be excluded, for example, experiments on ultraviolet photoreactions of psoralen with DNA, which proceed according to the scheme of Fig. 3*b*⁴³.

Psoralen can intercalate between the pairs of bases of double-stranded nucleic acids, forming covalent adducts with the pyrimidine bases on the absorption of a long-wave ultraviolet quantum. If there is another pyrimidine base on the opposite side, it can also form a second covalent adduct on absorption of a second photon by psoralen. The diadduct thus formed acts as an interstrand crosslink. Where irradiation lasts long enough there is always a large proportion of lethal cross-links which make it difficult to conduct experiments *in vivo*. Irradiation with a single short ultraviolet pulse, however, can be made to yield only monoadducts, as the psoralen molecule can absorb a second photon only after relaxing to the ground state through a triplet state; this takes longer than the pulse duration.

It is precisely by this method that the proportion of mono- and diadducts in the psoralen-DNA photochemical reaction have been controlled following irradiation with a short (15 ns) pulse of an N_2 -laser ($\lambda = 337 \text{ nm}$)⁴⁴. When using a pulsed radiation of a shorter wavelength (a KrF laser, $\lambda = 248 \text{ nm}$), which could be absorbed by the nucleic acid bases themselves, the formation of crosslinks occurred between RNA polymerase and DNA⁴⁵. Again, the use of short ultraviolet laser pulses is advantageous. Photodamage can be caused rapidly, but no structural changes are possible during the time of a single pulse.

Recently, a low-intensity (non-coagulative) He-Ne laser radiation ($\lambda = 632.8 \text{ nm}$) has been successfully used in clinical practice for treating wounds and trophic ulcers^{46,47}. The therapeutic effect of red laser light is frequently explained by its coherence. This argument seems unconvincing, however, as the molecular excitation rate W_{exc} is at least a factor of 10^{10} lower than the rate at which the excited molecules lose their coherence in a condensed medium at normal temperature⁴⁸. Experiments are under way to study this biostimulative effect at the level of mammalian cells, yeasts and bacteria, which have shown that the effect is present regardless of the coherence of the light used, provided its wavelength lies in the appropriate range, 600–850 nm⁴⁹. Thus, this biostimulative effect has no specific relation to the laser and should be considered simply a photobiological effect with useful applications to phototherapy.

Multiple-quantum excitation. The idea that multiple-quantum excitation of biological molecules can be produced by ultra-short laser pulses of low energy but high-peak power was formulated⁵⁰ immediately after such processes had been observed in the gaseous phase (see refs 12, 38). An intrinsic difference in the

Fig. 4 Simplified diagram of primary photoprocesses occurring in picosecond two-quantum excitation of biological molecules (thymine, a DNA base) in water. Absorption of two ultraviolet photons results in excitation of the S_N Rydberg state lying above the ionization threshold of both the dissolved molecule and water. $\tau_1 = 10^{-12}$ and $\tau_2 = 10^{-13}$ s are the non-radiative relaxation times for the states S_1 and S_N ; $\tau_3 = 10^{-11}$ and $\tau_4 = 5 \times 10^{-12}$ s are the times of formation and recombination of an electron-ion pair; $\tau = 10^{-12}$ s is the time of electronic energy transfer from the dissolved molecule to water. Subsequent ionization and dissociation of water ($\tau_5 = 10^{-13}$ – 10^{-12} s) leads to the formation of reactive radicals. Chemical reactions involving water radicals ($\tau_6 \approx 10^{-6}$ s) are the main photomodification channel for the dissolved molecules.

case of biological molecules in solution is the rapid non-radiative decay of their excited states. The situation is less critical if the molecule relaxes through a triplet state with a comparatively long lifetime (10^{-6} – 10^{-9} s). In this case, a two-step excitation can be effected by means of nanosecond laser pulses (Fig. 3c). However, for the molecule to absorb a second photon from a singlet state, its excitation rate must be close to the relaxation rate that lies in the picosecond range $1/\tau_{rel} \approx 10^{11}$ – 10^{12} s $^{-1}$. Such a two-step excitation can, therefore, be effected only by means of ultra-short laser pulses.

The first successful experiments on the two-quantum excitation of such molecules with picosecond laser pulses and the ensuing photoreactions were conducted with aqueous solutions of nucleic acid bases^{51,52}. As a result of such irradiation, the molecule absorbs two ultraviolet photons ($\lambda = 266$ nm) with a total energy of $2h\nu = 9$ eV which exceeds the ionization and dissociation limit of the molecules of the solvent, water. (Note that the direct one-quantum excitation to the same state ($\lambda = 133$ nm) is impossible because of the strong absorption of water in the ultraviolet.) The highly excited molecules may themselves undergo ionization with a yield that largely depends on the competition between the two-quantum photoionization and recombination processes (Fig. 4). Another possibility is the transfer of excitation to the molecules of the solvent, H_2O , which are subsequently ionized and dissociate⁵³. As a result of this process, the water molecules are decomposed into radicals that react with the dissolved biological molecules. Therefore, when using the two-quantum method to excite high-lying electronic states of biomolecules (for example, thymine) one can observe photobiochemical reactions that usually occur in solution in response to ionizing radiation⁵⁴. However, the ultraviolet picosecond photolysis of biomolecules has several advantages over their γ -radiolysis.

One principal distinction between two-quantum photolysis and γ -radiolysis is that the solvent molecules in the former case are dissociated only near the chromophore molecules which absorb laser radiation, and not within the entire irradiated volume, as is the case with γ -radiolysis. This fact is used to advantage in the laser therapy of tumours, for it provides the possibility of locally producing water radicals that kill tumour cells but have no effect on nearby normal cells, by means of specific sensitizer molecules.

Two-quantum photobiochemical reactions have been observed at various levels of organization in biological systems (for example, in viruses, yeasts and cells)^{55,56} (see ref. 57 for a review). This approach will apply in genetic engineering, especially in combination with microirradiation of cells⁵⁶. For

Fig. 5 Various degrees of heating of a substance with the laser radiation that underlie the various laser surgery techniques in ophthalmology.

instance, various types of molecular damage (for example, breaks, crosslinks) have been observed in nucleic acids *in vivo*^{55,57}. This allows the investigation of the spatial organization and functions of complex molecules such as proteins and nucleic acids, especially where effective methods for identifying damage sites are available⁵⁸.

In addition to the direct two- (multiple-) quantum process in biological molecules (following the scheme in Fig. 3c), one can use laser action with the help of sensitizer molecules, which absorb laser photons more effectively. These sensitizers are generally dyes which can form complexes with biological molecules. Once the sensitizer molecule has absorbed enough energy, the biological molecule suffers damage at the spot where the complex has been formed. This method has been investigated in experiments with nucleic acid molecules^{59,60}. For example, polyadenylic acid molecules undergo scission at the point of complexing with the dansyl derivative of oligothymidilate (DDO) under the effect of a powerful N_2 -laser pulse. This phenomenon is caused by the two-quantum excitation of DDO and subsequent transfer of excitation to the nucleic acid⁶⁰. It has been suggested that molecular sensitizers might be used to disrupt nucleic acid molecules at definite, pre-selected points^{60,61}.

The two-quantum excitation of high-lying electronic states is expected to increase considerably the yield of photoreactions compared with the known one-quantum reactions proceeding through triplet states, because the singlet-triplet conversion yield is in many cases much less than 100%. Such an increase in the yield of a photochemical reaction has been observed in experiments on the excitation of porphyrin molecules in solution⁶². Changing from a low-intensity excitation (<1 W cm $^{-2}$) to a high-intensity excitation (10^9 W cm $^{-2}$) increased the quantum yield of photomodification of porphyrin by a factor of 100. Similar experiments with a haematoporphyrin derivative, conducted with the N_2 -laser, showed⁶³ that the primary mechanism responsible for the destruction of this molecule was its two-step excitation. Such excitation produces a stronger cytotoxic effect than low-intensity irradiation.

Summarizing the first results of multi-quantum excitation of biological molecules, we are close to the development of new effective nonlinear laser phototherapy techniques using ultra-short laser pulses capable of producing considerable photochemical effects at an average power too low for thermal effects. In particular, a wide-ranging phototherapy method will probably be developed, based on the transfer of excitation to water molecules⁵⁴, which will extend the capabilities of the existing radiotherapy techniques.

Laser surgery

The use of lasers in surgery is based mainly on the absorption of a substantial amount of light energy in the area being operated on, which causes the heating of the irradiated region and its subsequent destruction by one of several possible mechanisms,

depending on the irradiation conditions. Such photodestruction of the tissue requires no contact, allowing absolute sterility for laser surgery. Second, by properly selecting the laser wavelength, one can attain a certain selectivity of photodestruction, provided that the tissue to be removed differs in absorption spectrum from the surrounding tissues. Third, the thermal effects can be varied over a very wide spectrum, from liquefaction without evaporation⁶⁴ under slight heating to destruction by hydrodynamic shock wave resulting from local intense pulsed heating⁶⁵. Finally, the laser irradiation region can be localized down to a few fractions of a micrometer, which enables organs to be operated on and microsurgery at the subcellular level⁶⁶.

The vast field of laser surgery is summarized briefly here, using ophthalmology as an example (Fig. 5). A continuous wave CO₂-laser radiation can be used to heat the surface layer of the vitreous humour of the eye from the ambient temperature to the gel liquefaction temperature and then to aspirate the liquefied area. In this case, the energy consumed in liquefaction (53 cal g⁻¹) is about one-tenth of that required for evaporation (576 cal g⁻¹). By increasing the radiated power, intense heating and coagulation of the irradiated region can be achieved. This is used, for example, in the treatment of proliferative diabetic retinopathy by photocoagulation⁶⁷. Focused laser radiation can be used to heat intensely and evaporate small areas inside the eye to open up a pathway into Schlemm's canal in treating glaucoma⁶⁸. In such microsurgical operations, it is essential that photodamage is strictly localized, to avoid intense heating and damage to the surrounding tissues. In this case it is advantageous to use a short, powerful laser pulse which, because of the nonlinear effect occurring at the focal point, can be absorbed even in a transparent tissue. This causes intense local heating and destruction in the area affected by the shock wave resulting from high hydrodynamic pressures; the surrounding tissue suffers no appreciable heating⁶⁵.

The field of application for laser-surgery techniques has been extended with the development of methods to deliver a surgical radiation dose (from a few watts to a few tens of watts) through an optical fibre passed through blood vessels to internal areas of the human body. Laser-angioplasty techniques^{69,70}, in which a fibre optics catheter is used to deliver a laser radiation to atherosclerotic obstructions (plaques) are particularly promising. To evaporate a plaque, it is sufficient to irradiate it by an argon laser of 3–4 W in power output for a few seconds, and the evaporation of a calciferous plaque requires 30–40 s of irradiation with the same laser. The destruction of an obstruction using infrared or visible CW radiation occurs according to a thermal mechanism, and to prevent thermal damage to the vessel walls, one is restricted to piercing only a small-diameter passage. Of interest, therefore, is the change from thermal destruction with CW laser radiation to photochemical ablation of plaques by pulsed ultraviolet radiation. In such photochemical actions, the radiation energy is expended directly in the breakdown of chemical bonds, followed by the destruction of the irradiated material as a result of volatile products⁷¹. Some preliminary reports on the effect of ultraviolet-laser radiation on atherosclerotic plaques *in vitro* show that the mechanism of action here is distinct from the thermal mechanism in visible and infrared irradiation⁷². This conclusion is in line with the results of studying the mechanism and products of plaques destruction by ArF ($\lambda = 193$ nm)⁷³, XeCl ($\lambda = 308$ nm) excimer and other lasers⁷⁴. The specific photo-ablation energy amounts to around 250 cal g⁻¹, that is, it is less than the specific thermodestruction energy⁷⁴. Thus, another promising method can be added to the list of potential photodestruction techniques in laser surgery.

Finally, sharp focusing of laser radiation (microbeam techniques) makes it possible to alter selectively some part of a subcellular organelle in a single living cell⁷⁵. The region of such alterations can be only a quarter of a micrometre in length. The laser wavelength and pulse duration can be varied over a broad range, allowing for photodestruction conditions, from thermal to multiquantum photochemical. This opens up new possibilities

in cell and developmental biology, enabling chromosome microsurgery, surgery of mitotic organelles and cytoplasm⁷⁵, for example. The capabilities of the technique extend into genetic engineering, as it provides experimentalists with a laser scalpel enabling a submicron hole to be pierced in the wall of a cell. The desired gene from the surrounding solution can enter the cell through this hole which is then healed again in a few fractions of a second⁷⁶ (J. Wolfrum, personal communication).

Thus, laser biology and medicine now use all the characteristics of laser light as well as all types of its interaction with biological structures. The many fascinating and rapidly developing laser applications are sure to become more widespread and diverse in the future.

I thank Drs T. Karu and D. Nikoglyan for their assistance and fruitful discussions in the course of preparation of the manuscript.

ARTICLE

Loss of heterozygosity in three embryonal tumours suggests a common pathogenetic mechanism

Children with the Beckwith-Wiedemann syndrome have a greatly increased potential for the specific development of the embryonal tumours hepatoblastoma, rhabdomyosarcoma and Wilms' tumour. Data obtained with molecular probes suggest that the association between these disparate, rare tumour types reflects a common pathogenetic mechanism that entails the somatic development of homozygosity for a mutant allele at a locus on human chromosome 11.

EMBRYONIC tumours in children may result from a developmental disturbance during organogenesis that causes arrest at an early stage in the normal differentiation process to adult tissue¹. This embryonal tissue continues to proliferate inappropriately at this early stage and produces a mass of immature tissue that has been simultaneously termed an embryonal tumour and an organismal malformation². Thus, these tumours can reasonably be considered to comprise one class of congenital malformations. The high-frequency association among some of these malformations has allowed clinical classifications of the developmental anomaly syndromes³. One example of this clinical grouping is the autosomal dominant Beckwith-Wiedemann syndrome (BWS)^{4,5}, which is composed of multiple congenital malformations coupled with a concurrent high risk for the development of specific rare childhood tumours. More than 10% of all individuals with BWS will develop one of the specific oncogenic malformations, which include Wilms' tumour, hepatoblastoma, rhabdomyosarcoma and adrenal carcinoma, in association with the growth excess disorders that characterize the syndrome^{5,6}. Even those individuals with the incomplete, partially penetrant form of the syndrome who display only a subset of these physical anomalies have increased risk for the development of specific malignancies⁶. In fact, these patients may develop tumours of more than one type simultaneously, such as the appearance of Wilms' tumour with adrenal carcinoma⁷ or adrenal adenoma⁸. Similar simultaneous development of more than one tumour type in patients with no readily apparent organismal anomalies has also been described. These include the development of Wilms' tumour with rhabdomyosarcoma⁹ or hepatoblastoma¹⁰, hepatoblastoma with adrenal adenoma¹¹, and rhabdomyosarcoma with adrenal carcinoma¹².

The suggestion of the ontogenetic relatedness of these tumour types is also supported by histopathological analyses. The embryonal tissue from which Wilms' tumour seems to arise

consists of the metanephric blastema that has failed to undergo the normal maturation process¹³. A common aetiology for Wilms' tumour, hepatoblastoma and rhabdomyosarcoma is suggested by the ability of these embryonal tumours to undergo divergent differentiation to form a tissue that does not occur in the normal end-stage organ. For example, fetal rhabdomyomatous nephroblastoma is a variant Wilms' tumour comprising striated muscle of the kidney¹⁴. The rhabdomyoblasts appear to arise by divergent or aberrant differentiation from the metanephric blastema¹⁴. Rhabdomyomatous tissue has also been observed in some hepatoblastomas¹⁵. Additionally, heterotropic primary tumours apparently consisting of adrenal carcinoma and rhabdomyosarcoma have been observed in surgically excised livers^{16,17}.

It has been reported that the expression of recessive mutant alleles at the *WAGR* locus on human chromosome 11 band p13 and the *Rb-1* locus on human chromosome 13 band q14 are involved in the development of Wilms' tumour¹⁸⁻²¹ and retinoblastoma²², respectively. Expression of the initial predisposing recessive mutation at these loci is effected by abnormal somatic chromosomal segregation events whose net result is the complete loss of the dominant balancing wild-type allele. The mitotic mechanisms that accomplish this removal included nondisjunctional loss and mitotic recombination. The results of these mitotic events are consistent with the production of a cell homozygous for the mutant allele at the retinoblastoma or Wilms' tumour locus. Evidence in support of this interpretation was recently obtained by the demonstration that the chromosome 13 homologue remaining in familial retinoblastoma tumours was always derived from the affected parent²³.

The clinical association of Wilms' tumour with other specific rare tumours in the presence of the growth excess syndromes, the development of more than one rare tumour in the same individual, and the presence of heterotropic tissue in these tumours could be simply circumstantial. Alternatively, these clinical associations may reflect a common aetiological event so that each of the developmental anomalies, including the tumours, arises after mutation of the same locus. Such mutations

Methods. DNA was isolated from normal tissue (peripheral leukocytes), surgical specimens of primary tumour or from a xenograft of the primary tumour passed twice in immunodeficient nude mice (NM), as described previously^{18,22,26}. DNA was also isolated from xenograft tumours derived from right and left lung metastases (passages 3 and 1, respectively) removed from patient B following thorotomy and wedge resection to remove metastatic hepatoblastoma nodules. DNA from each of these tissues was digested to completion with the indicated restriction endonucleases, subjected to agarose gel electrophoresis and transferred to Zeta-por membranes (AMF-Cuno) in 1.5 M NaCl/0.15 M sodium citrate. The membranes were prehybridized at 42 °C for 16 h in 0.75 M NaCl/0.075 M sodium citrate, 0.2% Ficoll 400, 0.2% bovine serum albumin (BSA), 0.2% polyvinylpyrrolidone, 50 mM sodium phosphate pH 6.7, 100 µg ml⁻¹ denatured salmon-sperm DNA and 50% formamide. The samples were hybridized to four recombinant DNA probes physically homologous to loci unique to the subregion p15 of the short arm of human chromosome 11 (ref. 34), reveal restriction fragment length polymorphisms and exhibit close genetic linkage³¹. The probe pHins-310, homologous to the insulin gene³⁵, and the probe pTBB-2, homologous to the c-Ha-ras-1 gene³⁶, exhibit polymorphic alleles of various lengths, generated by insertions or deletions of DNA sequences, in *PvuII*- and *TaqI*-digested DNA, respectively³⁴⁻³⁶. The probe JW151 is homologous to the β -globin gene cluster³⁷ and reveals restriction fragment length alleles of the γ^G portion of the locus of 8.0 and 7.2 kilobases (kb) and alleles of 3.5 and 2.7 kb at the γ^A portion of the locus in *HindIII*-digested DNA³⁷. The probe pADJ-762, an arbitrary genomic DNA segment, reveals alleles of 2.3 and 1.8 kb in *MspI*-digested DNA and of 11.6 and 4.2 kb, as well as a constant 6.9 kb band, in *BclI*-digested DNA³³. The ³²P-labelled nick-translated probes were hybridized to the membranes at 47 °C for 24 h in 0.75 M NaCl/0.075 M sodium citrate, 0.02% Ficoll 400, 0.02% BSA, 0.02% polyvinylpyrrolidone, 20 mM sodium phosphate pH 6.7, 100 µg ml⁻¹ denatured salmon-sperm DNA, 10% dextran sulphate and 50% formamide. The membranes were washed once at room temperature in 0.3 M NaCl/0.03 M sodium citrate/0.1% SDS for 30 min and then twice for 30 min each at 65 °C in 0.015 M NaCl/0.0015 M sodium citrate/0.1% SDS. The membranes were then exposed to Kodak XAR-5 X-ray film backed with Dupont lightning-plus intensifying screens for 1-3 days. Alleles at each locus are designated 1 or 2 according to decreasing length; C indicates a common, invariant band. Numbers to the right of each autoradiograph indicate the molecular size of the indicated allele in kilobases, derived from the standards run with each gel.

could be revealed by mitotic segregation events, similar to those demonstrated previously for Wilms' tumour¹⁸⁻²¹ and retinoblastoma²², which would serve specifically to produce hepatoblastoma, rhabdomyosarcoma and adrenal carcinoma tumours that have lost constitutional heterozygosity. In particular, if such homozygosity was specifically obtained for chromosome 11p, the data would imply that the Wilms' tumour locus plays a pleiotropic role in developing embryonic kidney, liver, adrenal and muscle tissue, perhaps by differential stage-specific expression. Such data would also indicate a limited number of genetic loci in which recessive mutations play a role in tumour development, each with specificity for a larger subset of tissue types. To distinguish between these hypotheses, we performed studies similar to those described previously for retinoblastoma²² and Wilms' tumour¹⁸⁻²¹.

Hepatoblastoma development

Figure 1 displays the constitutional and tumour genotypes at loci on chromosome 11p for two hepatoblastoma patients. CHMC 429572 (Patient A) was diagnosed with embryonal hepatoblastoma at 6 years of age. He was constitutionally heterozygous (that is, displayed both parental fragment length alleles) at the two loci defined by pADJ-762 in *MspI*-digested DNA and pTBB-2 in *TaqI*-digested DNA. One of the alleles at each of these loci was missing in the primary hepatoblastoma biopsy tissue and in the first passage of the biopsy in an immunodeficient mouse (Fig. 1a). CHMC 410212 (Patient B) was diagnosed with embryonal hepatoblastoma at 1.2 years of age. She was constitutionally heterozygous at the three loci on

human chromosome 11p defined by pADJ-762 in *BclI*-digested DNA, pHins-310 in *PvuII*-digested DNA and the γ^A portion of the β -globin locus defined by JW151 in *HindIII*-digested DNA. Each of these loci had become homozygous or hemizygous in tissue obtained as a primary hepatoblastoma biopsy, in the primary tumour tissue transplanted twice in immunodeficient mice and in metastatic tumours from the right and left lungs of the same patient (Fig. 1b). A third patient, CHMC 304772, was diagnosed with hepatoblastoma with elements of hepatocellular carcinoma at 3.1 years of age. He was constitutionally heterozygous at the two loci defined by pADJ-762 in *MspI*-digested DNA and pTBB-2 in *TaqI*-digested DNA; both alleles at each of these loci were apparent in the tumour (data not shown).

These results are similar to those reported for Wilms' tumour¹⁸⁻²¹. The somatic loss of constitutional heterozygosity in the two hepatoblastoma tumours shown in Fig. 1 could be effected by abnormal mitotic events. Mechanisms that have been demonstrated include the non-disjunctional loss of the wild-type chromosome with reduplication of the mutant chromosome, non-disjunctional loss of the entire wild-type chromosome and deletion or loss of the region of the chromosome containing the marker loci¹⁸⁻²². To distinguish between these possibilities, DNA samples from the normal tissues and primary tumour biopsies described in Fig. 1 were hybridized concurrently with a DNA probe homologous to loci on chromosome 11 (pADJ-762) and chromosome 17 (DOSLC4) (ref. 24). The resultant hybridization signals were analysed by quantitative densitometry (Table 1). The peak area obtained with each signal was calculated and the ratios of the signal unique to chromosome 11 to that unique to chromosome 17 were compared between the normal and tumour

Fig. 2 Loss of constitutional heterozygosity at loci on human chromosome 11p in rhabdomyosarcoma; *a*, patient A; *b*, patient B. **Methods.** *a*, Normal-tissue DNA was isolated from peripheral leukocytes and tumour DNA isolated directly from the primary tumour specimen obtained at surgery. *b*, Normal-tissue DNA was isolated from peripheral leukocytes; tumour DNA was isolated from a first passage xenograft of the primary tumour (NM). The conditions for digestion of the DNA samples, electrophoresis, Southern transfer to nylon membranes, hybridization and autoradiography were as described previously^{18,22,26} and are detailed in Fig. 1 legend. Alleles at each locus are designated 1 or 2 according to decreasing length; C indicates a common, invariant band. Numbers to the right of each autoradiograph indicate the molecular size of the indicated allele in kilobases, derived from standards run with each gel.

tissues. In each case, these ratios were similar in the two tissues, indicating that the loci on chromosomes 11 and 17 were present in both normal and tumour tissue in the same copy number. These data indicate that the tumour specific losses of constitutional heterozygosity described for the hepatoblastomas in Fig. 1 were effected by non-disjunctional loss of the wild-type chromosome with reduplication of the mutant chromosome rather than by chromosomal loss or deletion. It is also possible that loss of heterozygosity at the loci tested here, all of which map to the telomeric portion of chromosome 11, could arise by mitotic recombination between the centromere and the marker loci. We are not presently able to distinguish between the recombination and loss/reduplication mechanisms; such distinctions await the development of probes homologous with loci between the mutant hepatoblastoma locus and the centromere.

Rhabdomyosarcoma development

Figure 2 displays constitutional and tumour genotypes of two rhabdomyosarcoma patients. CHMC 401999 (Patient A) was diagnosed with embryonal rhabdomyosarcoma at 0.8 years of age. She was constitutionally heterozygous at the two loci defined by pADJ-762 in *MspI*-digested DNA and pHins-310 in *PvuII*-digested DNA. CHMC 421994 (Patient B) was diagnosed with embryonal rhabdomyosarcoma at 1.1 years of age. She was constitutionally heterozygous at the loci homologous to pTBB-2 in *TaqI*-digested DNA and pHins-310 in *PvuII*-digested DNA.

Table 1 Densitometric dosage analysis of DNA from normal leukocytes and primary tumour biopsies from hepatoblastoma and rhabdomyosarcoma patients

Patient	Tissue	Chromosome 11 chromosome 17	Tumour normal
CHMC 429572	Leukocytes	2.84	1.12
	Hepatoblastoma	3.20	
CHMC 410212	Leukocytes	1.16	1.03

Normal and tumour DNA from the patients described in Figs 1 and 2 were digested with the restriction endonuclease *BclI*, transferred to nylon membranes and hybridized simultaneously to the radiolabelled probes pADJ-762 and DOSLC4, as described in Fig. 1 legend. These probes are homologous to unique loci on human chromosomes 11 (ref. 33) and 17 (ref. 24), respectively. The resultant autoradiogram was analysed by scanning densitometry and the peak areas corresponding to each hybridization signal were calculated by electronic integration. The peak areas specific to chromosomes 11 and 17 were compared in each sample and these normalized values were compared for each tumour/normal tissue pair.

Only one of the two codominant alleles at each of these loci was apparent in the primary tumour biopsy from Patient A and in the first-passage xenograft of the primary rhabdomyosarcoma from Patient B. Patient CHMC 405680 was diagnosed with alveolar rhabdomyosarcoma at 3.3 years of age. He was constitutionally heterozygous at the two loci on chromosome 11p15 defined by pADJ-762 in *BclI*-digested DNA and pTBB-2 in *TaqI*-digested DNA; heterozygosity was maintained at both loci in the corresponding tumour sample (data not shown). DNA isolated from normal and tumour samples from patients A and B was hybridized to DNA probes homologous to loci on chromosome 11 (pADJ-762) or chromosome 17 (DOSLC4). Densitometric analysis of the resultant autoradiographic signals, as described above for the hepatoblastoma cases, is shown in Table 1. Again, the number of copies of the two loci was similar in the normal and tumour tissues, indicating that the loss of constitutional heterozygosity in the tumours was effected by a mitotic mechanism which resulted in loss of the wild-type chromosome 11 homologue with maintenance and reduplication of the mutant chromosome, rather than by simple chromosomal loss or deletion of the segment of the chromosome containing the marker loci.

Chromosomal specificity

The somatic losses of constitutional heterozygosity described above for hepatoblastoma and rhabdomyosarcoma, and previously for Wilms' tumour¹⁸⁻²¹, could serve specifically to unmask initial predisposing mutations on chromosome 11 as shown previously for chromosome 13 in retinoblastoma^{22,23}. Alternatively, the attainment of chromosome 11 homozygosity in these tumours might represent a portion of a generalized loss of heterozygosity, such as that proposed based on analyses of isozymic alleles²⁵. To distinguish between these possibilities, the Southern transfers shown in Figs 1 and 2 were treated with alkali to remove the chromosome 11 probes²⁶ and then hybridized to several probes that reveal restriction site polymorphism on other human autosomes^{24,26-28}. In every case where constitutional heterozygosity was present, both codominant alleles could be distinguished in the corresponding tumour tissue (Table 2). Thus, the tumour from patient CHMC 429572 maintained heterozygosity at loci mapped to chromosomes 13, 14 and 22; the tumour from patient CHMC 410212 for loci mapped to chromosomes 6 and 13; and the tumours from patients CHMC 401999 and CHMC 421994 for loci mapped to chromosomes 13 and 20. In total, these tumours, which had become homozygous at several loci on chromosome 11, retained heterozygosity at other loci on chromosomes 6, 13, 14, 20 and 22. These data indicate that the losses of constitutional heterozygosity for chromosome 11 in these tumours are specific events rather than part of a generalized loss during tumorigenesis. The maintenance

Tumour and normal DNA from hepatoblastoma patients CHMC 429572 and CHMC 410212, as well as rhabdomyosarcoma patients CHMC 401999 and CHMC 421994, were digested with appropriate restriction endonucleases, transferred to nylon membranes, hybridized to the indicated ³²P-labelled probes, washed and exposed to X-ray film as described in Fig. 1 legend. Each of the probes is homologous with a locus on the indicated chromosome^{24,26-28}. Tumour samples were: T¹, primary surgical biopsy; T², first passage xenograft of T¹; T³, primary surgical biopsy; T⁴, second passage xenograft of T³; T⁵, third passage xenograft of metastatic T³ excised from the right lung; T⁶, first passage xenograft of metastatic T³ excised from the left lung; T⁷, primary surgical biopsy; T⁸, first passage xenograft. In all cases, normal tissue was obtained as peripheral leukocytes. N, normal tissue; T, tumour tissue; ND, not determined.

Tumour and normal DNA from Ewing's sarcoma patients CHMC 319634, CHMC 414222 and CHMC 434672, as well as osteogenic sarcoma patients CHMC 438160, CHMC 428687 and CHMC 434642, were digested with the indicated restriction endonucleases, transferred to nylon membranes, hybridized to the indicated radiolabelled probes, washed and exposed to X-ray film as described in Fig. 1 legend. Tumour (T) samples were xenografts of primary surgical biopsies except in the case of CHMC 434642 where primary surgical biopsy material was obtained. Normal (N) tissue was obtained as peripheral blood leukocytes. ND, not determined.

of heterozygosity in these tumours for loci mapped to chromosome 13 is of particular interest because the same markers have previously allowed detection of retinoblastoma-specific losses of constitutional heterozygosity^{22,23}. The data described in Table 2 also provide assurance that the tumour-specific differences from constitutional genotypes shown in Figs 1 and 2 do not arise from simple mispairing of the samples. In fact, we have examined these samples at many more non-chromosome 11 loci than those shown in Table 2 and we have not observed any instance in which the homozygous alleles in each pair of tissues did not precisely match.

Tumour specificity

The previously described clinical data, as well as the specific loss of heterozygosity for loci on human chromosome 11 during the genesis of rhabdomyosarcoma and hepatoblastoma (described above) and Wilms' tumour¹⁸⁻²¹, suggest a pathogenetic mechanism shared by these three clinically associated tumour types. To determine whether these events are com-

mon among more than these three childhood cancers, we performed the analyses described in Table 3. We isolated DNA from normal and tumour samples obtained from three children each with Ewing's and osteogenic sarcoma. These DNA samples were then examined with the probes homologous to loci on chromosome 11, exactly as described in Figs 1 and 2. In each case, constitutional heterozygosity was maintained in these tumours. It has been reported previously²² that another pediatric tumour, retinoblastoma, maintained chromosome 11 heterozygosity in several tumour samples. These results suggest that the loss of constitutional heterozygosity in rhabdomyosarcoma, hepatoblastoma and Wilms' tumour is specific to chromosome 11 and also displays specificity in those childhood tumours in which it is a pathogenetic mechanism.

Discussion

Here, we have described molecular genetic evidence suggesting that human embryonal tumours reflect abnormalities in genes important to normal human organismal development. These

data unite two widely disparate classes of observation: the high-frequency clinical associations between rare tumours and congenital malformation syndromes³; and the specific somatic loss of constitutional heterozygosity in the oncogenesis of embryonal cancers¹⁸⁻²².

Our data suggest a common chromosomal pathogenetic mechanism in rhabdomyosarcomas and hepatoblastomas similar to that previously shown in Wilms' tumours¹⁸⁻²¹. These results imply a common aetiology in the genesis of these three embryonal tumours that involves pleiotropic expression of a mutant allele at the Wilms' tumour (*WAGR*) locus on human chromosome 11 band p13 (ref. 29). Chromosomal mechanisms that serve to unmask these recessive mutant alleles by elimination of the balancing wild-type homologue occurring at times specific to the development of kidney, liver or striated muscle could then result in an embryonal tumour specific to the developing tissue of the organ. Pathological observations showing that embryonal tumours maintain immature differentiation states imply that the product of the *WAGR* locus is necessary for the ordered progression of normal differentiation to occur. Failure to produce the gene product would then result in the persistence of precursor embryonal cells of each organ and thereby account for persistent renal blastema or nephroblastomatosis. The loss of function effected by aberrant chromosomal events at the various times in organismal development might explain the aberrant differentiation that is observed as heteroplasia^{14,15} in these tumours and that leads to the previously unexplainable presence of striated muscle precursors, rhabdomyoblasts, in embryonal tumours of the kidney (Wilms' tumour) and the liver (hepatoblastoma). Thus, several lines of clinical evidence suggest a pathogenetic association between these three embryonal tumours. It is not known whether this association results from differential expression of mutations in the same gene or represents overlapping deficiencies in a larger multigene complex. This distinction cannot be drawn until the gene(s) is isolated and analysed. Clearly, however, the genesis of each of these rare tumours involves the specific loss of constitutional heterozygosity for human chromosome 11 and these events occur in these clinically associated tumours and in none of the other embryonal tumours we have examined. Although we have not yet been able to examine adrenal carcinoma tissues, it is reasonable to propose, based on these findings and clinical observations^{5-8,11,12,17,18}, that this tumour also arises following the attainment of chromosome 11 homozygosity.

Most developmental anomaly syndromes associated with high risk for tumour development segregate in families with the characteristics of a single autosomal dominant mutation³. A genetic component in the aetiology of Beckwith-Wiedemann syndrome has been proposed based on its autosomal dominant mode of inheritance⁴ and by the observation of a constitutional karyotypic abnormality of human chromosome 11p (ref. 30) in

a few patients with the syndrome. These observations, taken together with the evidence reported here, are consistent with the idea that a genetic locus on the short arm of human chromosome 11 is involved in the determination of the phenotypic manifestations of this disorder, including the developmental and oncological malformations. The distinction between these two types of abnormalities may arise by differential requirements for the product of the normal locus at varying times of development. Alternatively, the developmental malformations may represent the heterozygote phenotype, whereas the various tumour types may arise only after the attainment of complete homozygosity for a mutant allele at the locus. Either of these possibilities implies that loci in which defects give rise to heritable groups of developmental disorders are also responsible for the oncological disorders associated with the syndrome.

These data also have broad implications for genetic mapping. They indicate that the number of genetic loci whose recessive mutant alleles predispose to cancer is more limited than might have been suspected based on previous studies¹⁸⁻²². Certainly, it does not now seem as if there is one such locus for each tumour type, but it is likely that these loci will have broader, but specific, tissue preference. Studies to identify loci similar to *Rb-1* and *WAGR* may now be designed more effectively by selecting tumour types based on their clinical associations. This approach has proved to be useful in this study and our preliminary studies show that retinoblastoma and osteosarcoma share both clinical association and a molecular pathogenetic mechanism. Conversely, the identification of which chromosome carries a recessive predisposing mutation by the kinds of comparisons of tumour and constitutional genotypes described here, in tumours which cluster with high frequency in the various developmental anomaly syndromes, may expedite the selection of genetic markers for pedigree analysis^{31,32}. For example, the identification of chromosomes that undergo specific losses of constitutional heterozygosity during oncogenesis of astrocytoma, medullary thyroid carcinoma and medulloblastoma may lead to localization of the genetic locus in their clinically associated autosomal dominant syndromes of neurofibromatosis, multiple endocrine neoplasia and basal cell nevus syndrome, respectively. These sorts of analyses may accelerate the development of recombinant DNA-based premorbid detection of these diseases.

We thank Drs M. Wigler, H. Kazazian, G. Bell, P. Pearson and R. White for kindly providing some of the molecular probes. We also thank Drs K. Bove, J. McAdams, J. Noseworthy, J. Neely and P. Dignan for their advice and interest; Marianne Brown and Erika Simon for technical assistance; and Juliann Hansen and Becky Howland for manuscript preparation. This work was supported in part by grants from the National Eye Institute (USPHS), the National Cancer Institute (USPHS) and the American Cancer Society.

Crystallographically aligned metal–oxide composite made by reduction of a directionally solidified oxide–oxide eutectic

A. Revcolevschi & G. Dhalenne

Laboratoire de Chimie Appliquée, Université Paris-Sud,
Bâtiment 414, 91405 Orsay Cédex, France

Aligned metal–oxide composite materials have been grown from the melt by directional solidification at eutectic composition of several binary metal–oxide systems. The resulting microstructures consist of metallic fibres $\sim 1\ \mu\text{m}$ in diameter imbedded in an oxide matrix^{1,2}. The occurrence of such fibrous structures, as opposed to lamellar structures, corresponds to eutectic compositions for which the volume fraction of the minor component is $<30\%$ (ref. 3). The work reported here presents a different route to the fabrication of aligned metal–oxide composites, making the production of fine-scale lamellar microstructures possible. The method consists of the chemical reduction of lamellar oxide–oxide eutectic structures in conditions of temperature and partial pressure of oxygen in which only one of the oxides is transformed to the corresponding metal. We show here how the method can be successfully applied to the preparation of aligned Ni–ZrO₂ lamellar structures.

Directionally-solidified oxide–oxide eutectics have been extensively studied in the past two decades, experimentation being carried out in more than 20 binary systems⁴. Several of them were examined in our laboratory within the framework of general studies of the structure and properties of oxide interfaces^{5–7}; these systems were chosen with the object of creating interfaces between a sodium chloride type structure (NiO) and other phases of cubic symmetry. The systems which were examined include: NiO–CaO (sodium chloride); NiO–NiAl₂O₄ (spinel); NiO–calcium-stabilized cubic ZrO₂ (fluorite); NiO–Y₂O₃ (fluorite-related).

Well-aligned eutectic microstructures were obtained and growth directions of the oriented structures, crystallographic relations existing between the two phases of each eutectic as well as the indices of the interface planes were determined^{8–10}.

It is of interest to extend these studies to metal–oxide interfaces by trying to reduce one of the oxides of an oxide–oxide eutectic structure into the corresponding metal. We chose the binary system NiO with stabilized cubic ZrO₂ because of the stability of ZrO₂ in conditions in which NiO could be easily

reduced into nickel. Another reason for this choice was the possible fabrication of a fine-scale structure made of alternate lamellae of ionically conducting (ZrO₂) and electronically conducting (Ni) phases.

Directional-solidification experiments in the NiO–ZrO₂ system were carried out in a floating-zone device¹¹. The starting rods which were used had a composition of 70 mol.% NiO, 25.5 mol.% ZrO₂, 4.5 mol.% CaO and were prepared by pressing (1 kbar) a mixture of finely ground 99.999% pure NiO, 99.9% pure ZrO₂ and 99.9% pure CaCO₃. The pressed rods, 12 mm in diameter, were sintered in air at 1,200 °C for 24 h before directional solidification was undertaken.

Growth experiments were performed in air. Optical examination of the microstructures indicate well aligned eutectic lamellar structures, the two phases of the eutectic being pure nickel oxide ($a_{\text{NiO}} = 4.178\ \text{\AA}$) and calcia stabilized cubic zirconia ($a = 5.13\ \text{\AA}$). The variation of the interlamellar spacing λ with the solidification rate R follows the law $\lambda^2 R = \text{constant}$, proposed by Tiller¹² and verified in many eutectic systems. Typically, for a growth rate of $1.5\ \text{cm h}^{-1}$, the interlamellar spacing is $\sim 3\ \mu\text{m}$ (Fig. 1).

Microfragments of the directionally solidified samples oriented along the growth direction were studied by rotating crystal, Weissenberg and Buerger precession methods, to determine preferred growth directions and epitaxial relations. Growth directions are mainly [110] for nickel oxide and [001] for calcia-stabilized zirconia: epitaxial relationships are [110]//[001] and (111)/(100), the interface planes being (111)_{NiO} and (100)_{ZrO₂} (ref. 13).

The information relative to growth directions of the eutectic phases was confirmed by X-ray diffractometry experiments carried out on transverse sections of the samples: the only peaks observed were high-intensity peaks corresponding to planes normal to growth directions, that is (220) for NiO and (200) and (400) for calcia-stabilized zirconia.

Directionally solidified samples, 3-mm thick, were submitted for 70 h to a chemical reduction treatment at 1,075 °C under a CO/CO₂ mixture (CO/CO₂ = 0.1) corresponding to $P_{\text{O}_2} = 1.6 \times 10^{-11}$ atmospheres, that is, conditions where NiO should be totally reduced to nickel¹⁴.

The microstructure resulting from reduction of the samples presented in Fig. 2 indicates that the aligned nature of the original eutectic structure and the cohesion between the two phases are maintained. Powder X-ray diffraction experiments on crushed samples show total reduction of NiO, the only observable lines being those of pure nickel ($a = 3.52\ \text{\AA}$) and of unaltered calcia-stabilized zirconia, the lattice parameter of which is the same as that found in the eutectic structure.

Fig. 1 Transverse section of the nickel oxide–calcium oxide–stabilized zirconia eutectic (70 mol.% NiO, 30% ZrO₂–CaO) solidified at $1.5\ \text{cm h}^{-1}$. Scale bar, $10\ \mu\text{m}$.

Fig. 2 Crystallographically aligned metal–oxide composite structure made by reduction of a directionally solidified oxide–oxide eutectic. Scale bar, $10\ \mu\text{m}$.

Fig. 3 Characteristic feature of a Ni-ZrO₂ sample showing presence of elongated cavities in the Ni phase. A crack can be seen on the left. Scale bar, 30 μ m.

In some areas of the samples, elongated cavities presumably caused by the elimination of oxygen from the nickel oxide phase can be observed in the nickel phase. A few cracks also occur, the region adjacent to these being depleted in cavities (Fig. 3), indicating cavity coalescence. Observation at higher magnification by scanning electron microscopy confirms these features and particularly the boundary coherence. A change in lamellar spacing on reduction was not detectable. This can be explained by the fact that despite the volume change when transforming from NiO to Ni, the resulting modification of lamellar spacing is theoretically small enough to lie within experimental error of the measurements.

X-ray diffractometry experiments performed on transverse sections of samples of oxide-oxide eutectic structure submitted to reduction by CO/CO₂ mixtures show, compared with the powder diffractograms of the same material, very strong (220) nickel and (200) and (400) zirconia peaks (Fig. 4).

Considering the above results concerning the orientation of the two phases of the NiO-ZrO₂ samples, it seems that the oriented nature of the ZrO₂ phase remains unchanged; the nickel phase seems also to be perfectly oriented, the (110) orientation of the nickel lamellae being that of the original nickel oxide phase. Taking into account the f.c.c. structure of nickel and the NaCl-type structure of nickel oxide, it appears that the reduction takes place by a topotactical process in which the departure of oxygen from the NiO phase leaves intact the f.c.c. nickel sublattice which contracts, preserving the monocrystalline nature of the nickel-based phase. This mechanism was confirmed by separate X-ray diffractometry experiments in which large monocrystalline NiO samples which were chemically reduced in the conditions described above showed transformation into mostly monocrystalline nickel.

These results may be compared with those obtained by Little *et al.*¹⁵ who examined by transmission electron microscopy (TEM) the early stages of low-temperature (200 °C) reduction of nickel oxide and observed the formation of both epitaxial and non-epitaxial nickel nuclei, the latter being limited in number at the beginning of the process but becoming predominant as reduction time progressed. Little *et al.* concluded that loss of epitaxy is a feature of the growth of the nuclei. The presence in our experiments of non-epitaxial nickel, if any, was minor, as indicated by Fig. 4b. One can rationalize the difference in behaviour observed in the two sets of experiments by the large temperature gap which separates them. At higher temperature, more nucleation would lead to small epitaxial nuclei which would rapidly coalesce into larger grains of quasi-iden-

Fig. 4 X-ray diffractometry of the material resulting from reduction of eutectic NiO-ZrO₂: a, powder pattern; b, transverse section of eutectic structure.

tical orientation. An additional reason for the retention of the nickel oxide orientation in nickel may be found in the crystallographic constraint provided by the ZrO₂ phase.

We have shown, therefore, that reduction of lamellar oxide-oxide eutectics may lead to fine-scale alternate metal-oxide structures. The preliminary X-ray studies indicate that, at least in the system under examination, the crystallographic relationships between the two phases of the original structure remain unchanged after reduction of one of the oxides. More elaborate X-ray and TEM studies are being performed to identify finally the Miller indices of the interface planes which apparently also remain unchanged, and second to better describe the Ni-ZrO₂ interface.

Continental volume and freeboard through geological time

G. Schubert & A. P. S. Reymer

Department of Earth and Space Sciences, University of California, Los Angeles, California 90024, USA

Approximate constancy of continental freeboard since the Archaean¹⁻³ has been used to argue that no growth of the continental crust occurred during the Proterozoic and Phanerozoic^{4,5} and that there was limited vertical movement of old cratons.⁶ However, it has been shown^{7,8} that constancy of freeboard implies net growth of the continental crust, because the ocean basins deepen as the heat flow from the mantle decreases with time (crustal thickness d_c , the volume of the oceans V_o and the Earth's surface area A_e being constant). A net growth of about 25% or 1 km³ yr⁻¹ is necessary to maintain freeboard at a constant value⁷. We further explore here the consequences of approximate constant freeboard for continental growth using a model that relates the volumes of

isostatically compensated continents and oceans to the secular decline in terrestrial heat flow. We find that a post-Archaeon increase in freeboard by 200 m requires continental growth of only 10%, while a decrease in freeboard by 200 m during this same period necessitates a crustal growth of 40%. Shrinkage of the continental crust since the end of the Archaeon can be ruled out. Changes of >10% in post-Archaeon crustal thickness are highly unlikely.

Temporal variations in freeboard (transgressions and regressions of sea level) can arise from melting of polar ice, post-glacial rebound, changes in the number and areal distribution of continental segments⁹, and changes in the volume of mid-ocean ridges and continents. We consider only the secular changes in freeboard due to changes in the area and thickness of the continents, and changes in the volume of the oceans particularly as a consequence of the deepening of the ocean basins with time on a cooling Earth.

There is an uncertainty of a few hundred meters in the difference between freeboard during the early Proterozoic and the present, mainly due to our inability to calibrate the significance or representativeness of present-day freeboard. The uncertainty in how freeboard has changed since the Archaeon, although small, has important consequences for crustal growth.

Continental crustal volume V_c is the product of its area A_c and thickness d_c . Ocean volume V_o is given by $V_o = A_o(d_a + d_b)$, where A_o is the area of the oceans, d_b is the mean depth below the level of the mid-ocean ridges (MOR) and d_a is the depth below sea level of the rise crests (Fig. 1). The areas of the oceans

Fig. 1 Sketch of the model. MOR, Mid-ocean ridge; ρ_m , mantle density; ρ_{cc} , crustal density; ρ_w , water density; h , continental freeboard.

and continents sum to the total surface area of the Earth. We assume that A_c has remained constant throughout geological time (the change in A_c due to whole Earth cooling is negligible); V_o is also taken to be constant since the end of the Archaeon. This assumes that all the water in the present oceans outgassed from the interior at the earliest stages of the Earth's evolution and that the amount of water in the form of ice and vapour was not substantially different 2,500-Myr ago from the amount at present.

Continents and oceans are assumed to have always been in isostatic balance. Application of the principle of isostasy¹⁰ to the model of Fig. 1 gives (see Fig. 1 for parameter definitions)

$$d_a - d_a^* = (d_c - d_c^*) \frac{(\rho_m - \rho_{cc})}{(\rho_m - \rho_w)} - (h - h^*) \frac{(\rho_m)}{(\rho_m - \rho_w)} \quad (1)$$

An asterisk indicates present-day values. Ocean-continent density differences extending to great depth in the mantle and varying through geological time could modify the isostatic balance. The connection¹⁰ between d_b and the mean oceanic surface heat flow q_s is

$$\frac{d_b}{d_b^*} = \frac{q_s^*}{q_s} \quad (2)$$

It is generally accepted that q_s has decreased monotonically through geological time through the gradual decline in radiogenic heating and the secular cooling of the Earth¹¹. The decrease tends to follow the decline in internal radioactive heat sources¹¹ and we have adopted a model¹⁰ of the decrease in heat production to derive the form of $q_s(t)$ shown in Fig. 2. Mean oceanic heat flow decreases by about a factor of 4 since 4,500 Myr ago; the decline since the end of the Archaeon is by a factor of ~2. We have ignored the small amount of mantle heat that escapes through the continents consistent with our simplified model and

Fig. 2 a, Assumed variations of crustal thickness and mean oceanic heat flow through geological time. b, Continental volume (as a percentage of present volume V_c^*) versus time before present for different assumed crustal thickness variations. c, Freeboard (as a percentage of its present value h^*) as a function of time for V_c and d_c constant. The parameter labelling the curves in b and c is the fractional increase in crustal thickness over 4,500 Myr. The dashed portions of the curves refer to the time period in Earth history when freeboard and crustal thickness are highly uncertain. If h is negative, the continents are flooded. Thus the intersection of the curves in c with the horizontal axis gives the time of emergence of the continents above sea level.

the large uncertainty in past surface heat flow. Figure 2 also shows two models of crustal thickening that we consider; the values 0.1 and 0.2 refer to thickness increases of 10- and 20% over geological time.

Our model relating crustal growth and continental freeboard is similar in many respects to the one studied by Wise¹. Our principal contribution is the addition of equation (2) and the recognition that the cooling of the Earth deepens the ocean basins and thereby has a major role in controlling freeboard.

For constant freeboard and crustal thickness

$$\frac{V_c}{V_c^*} = \frac{A_c}{A_c^*} \frac{(V_o/A_c^*)}{d_a^* + d_b^*(q_s^*/q_s)} \quad (3)$$

in agreement with our previous result⁷. The increase of V_c with time as a consequence of the decline in q_s is readily deduced from equation (3); $V_c(t)$ is shown in Fig. 3. Parameter values are summarized in Table 1; q_s^*/q_s is given in Fig. 2a. The curve labelled 0 in Fig. 2b is for $d_c = \text{constant}$ and shows that a 25%

Fig. 3 Freeboard variation with time during the Proterozoic-Phanerozoic for prescribed percentage changes in continental volume between 2,500 Myr ago and the present. Both crustal growth and shrinkage are considered. Crustal thickness is assumed to be constant.

post-Archaeon increase in crustal volume is necessary to maintain constant freeboard⁷.

Since constant freeboard requires 25% post-Archaeon crustal growth (with d_c constant), it is important to determine what change in freeboard would occur for V_c = constant. With both V_c and d_c constant,

$$h^* - h = \left(1 - \frac{\rho_w}{\rho_m}\right) \left(1 - \frac{q_s^*}{q_s}\right) d_c^* \quad (4)$$

Equation (4) shows that freeboard must have been smaller in the past. The decrease in q_s and the deepening of the ocean basins causes a secular regression in sea level, that is, an increase in freeboard. Figure 2c illustrates the variation in freeboard with time computed from equation (4) and the parameter values given in Table 1. At the end of the Archaeon, h is predicted to be only about 40% of its present value (curve 0); freeboard must have increased by 400 m. This seems inconsistent with the geological constraint of approximate constant freeboard, but it is difficult to estimate the uncertainty in this constraint quantitatively.

It is clear from the above that freeboard variations of only several hundred metres are associated with crustal volume variations of tens of per cent. Since freeboard changes of this magnitude cannot be ruled out on geological grounds we consider the general relation between h and V_c for constant d_c .

$$h - h^* = \frac{(\rho_m - \rho_w)}{(\rho_m)} \left[d_c^* + d_b^* \frac{q_s^*}{q_s} - \frac{V_0}{(A_c - V_0/d_c^*)} \right] \quad (5)$$

We have evaluated equation (5) for prescribed changes in continental volume between the end of the Archaeon and the present and show the results in Fig. 3.

As we have already seen, no change in freeboard implies crustal growth of 25% during the post-Archaeon. If freeboard has been within ± 200 m of its present value since the end of the Archaeon, then the continents have grown during the past 2,500 Myr by anywhere from ~ 10 to 40%. Crustal growth is required as long as freeboard at the end of the Archaeon was not more than 400 m smaller than it is today. Crustal shrinkage since the end of the Archaeon requires an increase in freeboard by at least ~ 0.5 km since 2,500 Myr ago. Although secular freeboard changes of several hundred metres since the end of the Archaeon might be consistent with the geological evidence, changes of 0.5 km or more probably can be ruled out. Therefore, we conclude on the basis of Fig. 3 that post-Archaeon crustal growth by a few tens of per cent is required.

Cooling of the Earth and deepening of the ocean basins tend to increase freeboard through geological time. Crustal shrinkage (with constant thickness) reinforces this trend. Figure 3 shows that shrinkage by even as much as 10% since 2,500 Myr ago would mean that the continents just emerged above sea level at the end of the Archaeon. Crustal growth offsets the tendency of deepening ocean basins to increase freeboard with time. If the crust has grown more than 25% since the end of the

Table 1 Values of model parameters

Parameter	Definition	Value
V_0	Volume of oceans	$1.17 \times 10^{18} \text{ m}^3$
V_c^*	Present volume of continents	$7.6 \times 10^{18} \text{ m}^3$
A_c^*	Present area of continents	$2.17 \times 10^{14} \text{ m}^2$
A_0^*	Present area of oceans	$293 \times 10^{14} \text{ m}^2$
A_s	Surface area of Earth	$5.1 \times 10^{14} \text{ m}^2$
d_s^*	Present depth of mid-ocean ridge system below sea level	2,500 m
d_b^*	Present depth of ocean basins below the rise crests	1,500 m
d_c^*	Present average crustal thickness	38 km
h^*	Present continental freeboard	750 m
ρ_m	Mantle density	$3,300 \text{ kg m}^{-3}$
ρ_w	Water density	$1,000 \text{ kg m}^{-3}$
ρ_{cc}	Crustal density	$2,750 \text{ kg m}^{-3}$

Archaeon, freeboard has decreased during the Proterozoic-Phanerozoic, that is, the continents would have had their maximum emergence at 2,500 Myr ago. This runs against most assessments of the geological and sedimentological records, which support a constancy^{1,2,4-6} or a slight increase¹² rather than a decrease¹³ in continental freeboard since $\sim 2,500$ Myr ago.

To assess how variations in crustal thickness might affect our conclusions, we consider how freeboard and continental volume are related for prescribed $d_c(t)$

$$h - h^* = \frac{(\rho_m - \rho_w)}{(\rho_m)} \left[\frac{(\rho_m - \rho_{cc})}{(\rho_m - \rho_w)} (d_c - d_c^*) + d_s^* + d_b^* \frac{q_s^*}{q_s} - \frac{V_0}{(A_c - V_0/d_c^*)} \right] \quad (6)$$

With $d_c(t)$ from Fig. 2a, we use equation (6) to determine freeboard (or continental volume) given an assumed variation in V_c (or h). It can be deduced from equation (6) that crustal thickening augments the deepening of the ocean basins with time by requiring even larger increases in crustal volume (compared with d_c constant) to preserve constant freeboard.

Figure 2b illustrates how crustal thickening by 10 and 20% since 4,500 Myr ago modifies the amount of crustal growth required to maintain constant freeboard. Even a small amount of crustal thickening greatly increases the quantity of crustal growth necessary for constancy of freeboard. For example, with 10% crustal thickening over all of geological time, continental volume would have to have doubled since the end of the Archaeon. The geological evidence argues against such a large post-Archaeon increase in V_c .

Figure 2c summarizes how the assumed crustal thickening influences freeboard for no crustal growth. With V_c constant, a thinner crust in the past implies a larger continental area and, therefore, a smaller freeboard than at present. With even small increases in d_c , the continents would not rise above the oceans until at least the mid-Proterozoic. An increase in d_c and a late emergence of the continents have been proposed¹⁴⁻¹⁶, but this is not supported by geological data². A drastic global increase in d_c by underplating¹⁶ neglects the freeboard constraint and hotspot frequency data⁷, but underplating could be applicable to rapidly formed crustal segments¹⁷. We conclude that post-Archaeon changes in mean crustal thickness are highly unlikely.

Some secular changes in h may have occurred which are not included in our model, but their analyses are not useful as long as no firmer constraints can be put on the 'error' in constant freeboard. A regression during the Phanerozoic has been proposed¹², but the amount depends on an arbitrary point in time from which detailed data are available and does not necessarily point to a regression since the Archaeon¹⁸. A 5% change in ocean volume corresponds to a 200-m change in sea level. Therefore, small secular changes in ocean volume cannot be excluded. Present estimates of water subducted in trenches and released at mid-ocean ridges vary widely¹⁹ and need revision. Changes with time in the thickness of ocean floor sediments, in

the depth to ridge crests, in oceanic crustal thickness and in the development of deep mantle roots under the continents may all influence freeboard. Lack of data limits the usefulness of incorporating these effects into our model and increases the overall uncertainty in our results.

The continents increased their size during the Proterozoic and Phanerozoic^{7,17}, indicating at least 20% growth since 2,500 Myr ago. Such a growth rate is close to the requirement for constant freeboard and encourages us to believe that ocean volume and crustal thickness have remained essentially constant since 2,500 Myr ago, with error margins as given above.

We thank Donald U. Wise for constructive comments. This study was done under NASA grant NAG-9-76 while A.R. was on a sabbatical leave from the Hebrew University of Jerusalem.

Sea-bed noises reveal role of turbulent bursting phenomenon in sediment transport by tidal currents

A. D. Heathershaw* & P. D. Thorne

Institute of Oceanographic Sciences, Crossway, Taunton TA1 2DW, Somerset, UK

In many engineering and sedimentological applications, it is usual to relate sediment movement to the time-averaged bed shear stress. However, the shear stress exerted on the sea bed by tidal currents is intermittent in nature due to the turbulent bursting phenomenon^{1,2}. Sediment movement at the sea bed also occurs in bursts^{3,4}. However, attempts to link these two processes have failed because of the poor temporal resolution of existing sediment-transport measurement techniques. Recent experimental advances now make this possible and we describe here the first detailed observations of sediment movement and fluid turbulence in tidal currents flowing over sandy gravels. These results show that high stress values are a necessary, but not sufficient, condition for bed-load sediment movement and that form drag on individual particles may have greater dynamical significance than the stress. This work also suggests that it may now be possible to describe sediment movement at a level which is deterministic in terms of the turbulence and at very much shorter timescales than have been used previously.

The importance of the bursting phenomenon in tidal current boundary layers has been confirmed in previous work^{1,2}. This has shown that, similarly to laboratory boundary layers^{5–8}, the bulk of the Reynolds stress is made up by contributions from large and intermittent momentum transporting events which, collectively with other weaker motions, comprise the bursting phenomenon. Here the Reynolds stress is defined as $\tau = -\rho u w$ where ρ is the fluid density, u and w are the horizontal and

vertical turbulent velocity fluctuations and the overbar denotes averaging in time. In particular, these early studies established that positive contributions to the stress were principally from two types of motion; ejections in which $u < 0$; $w > 0$ and sweeps in which $u > 0$; $w < 0$. In addition, two weaker motions, inward ($u < 0$; $w < 0$) and outward ($u > 0$; $w > 0$) interactions, made negative contributions to the stress. Note that the motions which contribute to the bursting sequence of events are generally considered to be associated with pairs of counter rotating vortices⁹. These, in turn, may be associated with a Taylor–Görtler instability¹⁰. However, the exact generation mechanism for the vortices and the bursting phenomenon is unknown⁹.

In parallel with the purely fluid dynamical interest, there has been considerable speculation^{11–14} over the exact role of the turbulent bursting phenomenon in sediment transport. However, only recently has the development of a passive acoustic technique made it possible to observe sediment movement with a temporal resolution comparable with the high frequency turbulence in the flow. In particular, it is possible to detect^{15–17} the self-generated noise (SGN) arising from interparticle collisions of mobile sediment and to relate the acoustic intensity to the amount and size of sediment which is moving. Thus, for the first time, it has been possible to make a detailed examination of the relationship between bed-load transport and the turbulent structure of the boundary layer near the sea bed.

During studies to examine the incipient motion of sea-bed gravels in the West Solent, on the south coast of England⁴, measurements have been made of the horizontal (u) and vertical (w) turbulent velocity fluctuations at a height of 0.33 m above the sea bed using electromagnetic current meters¹⁵. The water depth in the study area was ~14 m. Underwater television (TV) and a wideband (–3 dB ≈ 150 kHz) hydrophone were used to monitor the movement of sediments in the approximate size range 4–32 mm (ref. 4). The hydrophone was positioned at a height of 0.24 m above the sea bed. Turbulent flow and SGN data were recorded at 0.2-s intervals. (Further details of these measurements are given in refs 4, 15.)

Figure 1 shows measurements of the horizontal and vertical turbulent velocity fluctuations u and w , and their contribution $-uw$ to the Reynolds stress. Figure 1 confirms the presence of the bursting phenomenon in tidal currents flowing over gravels in the West Solent with instantaneous stress values which may be 10 or more times greater than the mean value obtained by averaging the stress over a typical record length of 1,200 s (Table 1). Figure 1 shows that the bursting phenomenon is uniquely identified by the large and intermittent contributions that it makes to the Reynolds stress. This intermittency occurs despite the fact that u and w are normally distributed and randomly fluctuating quantities when taken separately¹⁸. Figure 1 also shows the SGN signal, corrected for background noise, and illustrates that the bulk of the gravel movement occurs in bursts, during sweep type events. This is illustrated further in Fig. 2, which shows u , w , $-uw$ and the SGN signal on an expanded timescale. Figure 2a shows ejection type events ($u < 0$; $w > 0$) which produce no sediment movement while Fig. 2b shows sweep events ($u > 0$; $w < 0$) producing appreciable quantities of sediment movement. Underwater TV observations¹⁵ of gravel movement have provided an independent means of checking the performance of the SGN device as shown in Fig. 1. As far as we know this is the first description of observations of the type shown in Figs 1 and 2.

To examine in more detail the relationship between sediment movement and turbulent fluctuations in the Reynolds stress, comparisons have been made of the amounts of sediment movement occurring in the different types of Reynolds stress event. For these comparisons five records from the West Solent were chosen, corresponding to a period of decelerating tidal flow on 19 September 1982 (Table 1).

Acoustic intensity levels were compared with the stress ($-uw$) records, following linear trend removal from u and w , an empirically determined 1-s adjustment for lag effects due to the separation between the flow sensors and the sea bed, and possible

* Present address Ocean Science Division, Admiralty Research Establishment, Portland, Dorset DT5 2JS, UK.

Fig. 1 Records of the horizontal and vertical turbulent velocity fluctuations u and w , and their product $-uw$. Also shown is the SGN acoustic intensity record and qualitative estimates of gravel movement from the underwater TV. For clarity 1-s averages only of u , w and SGN are shown together with 5-s estimates of gravel movement from the underwater TV. Black stress events (S) correspond to sweeps ($u > 0$; $w < 0$) and white events (E) correspond to ejections ($u < 0$; $w > 0$).

particle inertia. The significant stress events in each record were identified using a procedure similar to that given in refs 19, 20. Stress events were ranked according to peak size and regardless of sign, in such a way as to make up a total contribution of 90% to the overall stress. Event duration was defined by forwards and backwards interpolation to give uw values which were 10% of each peak. Event amplitude was defined as the average of $-uw$ taken over the duration of the event. Average values of u , w and the acoustic intensity were also calculated over the same time interval. Stress events were then identified as ejections, sweeps and inward or outward interactions according to the sign of the u and w averages. In this way, the average acoustic intensity levels, and hence the quantity of sediment moved by the significant stress events in each record, could be categorized and compared. Further details of the amplitudes, durations and percentage contributions to the overall stress, for the various events, are given in Table 1.

The results of this analysis are shown in Fig. 3, which shows

comparisons for 3,187 events measured over a period of ~ 100 min. This demonstrates quite clearly (Fig. 3a, b) that acoustic intensity levels associated with sweeps ($u > 0$; $w < 0$) are substantially higher than the intensity levels during ejections ($u < 0$; $w > 0$) at high stress values. This difference increases as the stress ($|uw|$) increases. From this we conclude that of the two types of motion which contribute to the bulk of the Reynolds stress, ejections and sweeps (Table 1), only sweeps are capable of supporting appreciable sediment movement. However, an interesting and unexpected result is that outward interaction events ($u > 0$; $w > 0$), although weaker and less frequent than sweeps (Fig. 3e), are capable of supporting greater sediment movement in the stress range $0 < |uw| < 0.04 \text{ m}^2 \text{ s}^{-2}$. This is despite the fact that they make a negative contribution to the stress. Correspondingly, there is little sediment movement associated with inward interactions ($u < 0$; $w < 0$). On average, sweeps and outward interactions contribute $\sim 46\%$ of the overall stress and 73% of the total acoustic intensity in only 24% of the time.

U_{100} is the current at 1 m above the sea bed from near-bed velocity profile measurements. The water depth at this location was ~ 14 m. $-\overline{uw}$ is the overall kinematic stress. The Reynolds stress is given by $\tau = -\rho \overline{uw}$. All the records were obtained in the West Solent on 19 September 1982. Record lengths are 20 min with the exception of the record beginning 0944 h (AST) which is 17 min in length. E denotes ejections, S sweeps, OI outward interactions and II inward interactions. Values in parentheses are standard deviations except in the case of contributions to the stress where they indicate the proportions of time as a percentage.

Fig. 2 (Left) u , w , $-uw$ and SGN records on an expanded timescale showing: *a*, ejection-type events (E) which produce no sediment movement; and *b*, similar-size sweep (S) events (black) producing appreciable sediment movement. Inward and outward interaction events, II and OI respectively, are also indicated. Only 5-Hz data are shown.

Fig. 3 (Right) Comparisons of sediment movement due to sweeps (*a*), ejections (*b*) and outward and inward interactions (*c* and *d*). *a-d* show mean values of the acoustic intensity in each $0.01 \text{ m}^2 \text{ s}^{-2}$ interval of $|uw|$, plotted against the mean stress in the same range. The number of events comprising each mean value of the acoustic intensity is indicated in *e* and *f*. Observations with <2 events are not shown. Error bars correspond to ± 1 s.e.m. and are not shown for standard errors $<0.2 \text{ } \mu\text{W m}^{-2}$. Standard error bars for the stress were $<4\%$ of each mean and for clarity are not shown. The total number of events was 3,187.

These results suggest that horizontal turbulent velocity fluctuations (u) may have greater dynamical significance in terms of sediment movement, than the instantaneous contributions ($-uw$) to the Reynolds stress. However, vertical fluctuations (w) may still be important provided they are associated with increases in u . This seems to be the case for outward interactions (Fig. 3c), where $w > 0$ may indicate additional lift on exposed gravel particles by fluid moving away from the bed. This, in turn, may account for sediment transport rates which are higher than those in similar-size sweeps.

The observed close dependence on u could be explained if the gravel was moved principally by form drag acting on the flow-normal projected area of exposed particles. Sediment sampling²¹ has confirmed that the West Solent gravels are poorly sorted and underwater TV observations⁴ have shown that sediment movement is by sliding or rolling of exposed particles. To test this hypothesis, we have carried out correlation analyses on the acoustic intensity and turbulent flow records in Table 1, first in terms of the form drag proportional to $(\bar{U} + u)^2$, where $\bar{U}$ is the horizontal mean flow, and second in terms of contributions $|uw|$ to the Reynolds stress ($-puw$). The results of these comparisons are shown in Table 2 and indicate that in all cases sediment movement is better correlated with form drag than with the instantaneous stress. Note that although the correlation coefficients in Table 2 are low, they are, nevertheless, highly significant because of the very large number of data points in

each record (about 6,000). On average, Table 2 shows that the correlation (r) of sediment movement with $(\bar{U} + u)^2$ is a factor of two times better than that with $|uw|$.

Through the application of a novel acoustic technique, this work has provided a detailed high temporal resolution comparison of sediment response and turbulent flow conditions.

Table 2 Results of correlation analyses of SGN records with $(\bar{U} + u)^2$ and $|uw|$

Record (h)	Correlation coefficient (r) at 1 s lag SGN/ $(\bar{U} + u)^2$	SGN/ $ uw $
0924-0944	0.45	0.26
0944-1001	0.30	0.15
1024-1044	0.39	0.19
1044-1104	0.35	0.17
1104-1124	0.33	0.12

This has shown that bed-load movement of sea-bed gravels is caused principally by sweep-type motions in the bottom boundary layer and to a lesser extent by outward interactions. This observation can be explained if form drag rather than shear stress is assumed to be the principle cause of gravel movement. Furthermore, laboratory observations^{22,23} in steady currents have shown that the movement of finer sediments in suspension may also be linked to the turbulent bursting process. It is, therefore, interesting to speculate that a complete description of sediment movement in terms of the fluid turbulence might now be possible. In conceptual terms at least, this would consist of bed-load transport of coarse sediments driven principally by sweep-type events, while suspended load transport of finer sediments would be dominated by the ejection of low-momentum fluid away from the boundary. Beyond this, if sediment movement can be quantified in terms of the magnitude of sweep- and

ejection-type events, and if the frequency with which these motions occur can be predicted accurately⁹, then a new generation of sediment transport equations may be deduced which take the turbulent bursting process into account.

We thank J. M. Codd and A. A. Landa for assistance with computer programming and with the analysis of underwater TV data.

Hydrothermal particle plumes over the southern Juan de Fuca Ridge

Edward T. Baker, J. William Lavelle & Gary J. Massoth

Pacific Marine Environmental Laboratory, NOAA Building Number 3, 7600 Sand Point Way N.E., Seattle, Washington 98115, USA

Hydrothermal particles originate in buoyant plumes emanating from seafloor thermal vents¹⁻⁴ and accumulate as metalliferous sediments found along oceanic spreading centres⁵⁻⁷. Observational evidence of the transport pathway of hydrothermal particles is scarce, however, and the structure, extent and particle concentrations of hydrothermal plumes remain largely conjectural. To evaluate the potential of hydrothermal plumes as particle transport agents, we mapped their distribution along and across the 80-100-m-deep axial valley of the southern Juan de Fuca Ridge in the north-east Pacific Ocean ($\sim 44^{\circ}30'N$, $130^{\circ}W$), an area of known hydrothermal activity⁸⁻¹¹. Continuous light-scattering measurements, reported here, defined numerous particle plumes centred 30-120 m above bottom (m.a.b.); elemental analysis of the plume particles and the θ (potential temperature)- S (salinity) signatures of the plume water verified their hydrothermal origin. Concentrations of hydrothermal particles remained elevated at ridge-crest depths at least 100 km from the ridge, indicating distant off-axis dispersal of hydrothermal emissions.

Two-dimensional plume representations were constructed from continuous data acquired by an acoustically-tracked sensor package regularly cycled between 20 and 200 m.a.b. while being towed. Twenty-six tows along or across an 18-km segment of the axial valley were made between 27 May and 17 June 1984 (Fig. 1). Sensors on the tow body included an integrating scatterance meter (nephelometer), thermometer (resolution $\pm 0.0003^{\circ}C$), and conductivity cell (resolution $\pm 0.00004 S m^{-1}$). In addition to the tows, vertical conductivity-temperature-depth (CTD)/nephelometer/rosette casts over the ridge axis and up to 100 km off axis further defined plume distributions and collected particles for chemical analysis by secondary emission X-ray fluorescence¹² and for empirical calibration of the nephelometer. Relative light scattering values were linearly and significantly correlated (correlation coefficient, $r^2 = 0.86$) with mass con-

Fig. 1 The study area, circled in the inset, lies along the Gorda Ridge-Blanco Fracture Zone-Juan de Fuca Ridge rift system of the north-east Pacific Ocean. Selected tow tracks are shown relative to the floor of the flat axial valley (delimited by the 2,220-m contours) and the adjacent ridge crests (indicated by the thin dashed lines). The axial strike is $\sim 18^{\circ}$. Individual along-axis tow tracks can be identified by the key in Fig. 2b; cross-axis tracks are shown as thick solid lines. The locations of known active hydrothermal vents ($\circ$) as determined by deep-tow⁹ and submersible¹⁰ observations are shown along the centreline of the valley. Positions of moorings ($\blacktriangle$) and selected CTD casts ($\blacksquare$) are also shown. Sediment traps and current meters were located 50 m.a.b. on V4 and 100 m.a.b. on V5, an additional current meter was at 200 m.a.b. on V4.

centration determined by membrane filtration of 129 samples. Vertical particle flux (from sediment traps¹³) and current speeds were measured during the cruise on moorings in the axial valley (V4) and 4 km west of the valley (V5).

Each of the 26 tows found particulate plumes derived from hydrothermal emissions. The hydrothermal origin was indicated

Fig. 2 a, Relative light-scattering isopleths constructed from along-axis tows S20 and S26 taken 7 days apart. The sawtooth pattern shows the towpath. The light-scattering values (I_s) may be converted to mass concentration (C) by the empirical relationship $C(\mu\text{g l}^{-1}) = 69.2 I_s - 19.7$. Shaded areas indicate concentrations $>30 \mu\text{g l}^{-1}$. The distance scale is variable because the actual track line was 'serpentine' along the valley. The bottom depth increases from $\sim 2,230$ m at km -3 to $\sim 2,260$ m at km 12. b, Vertically integrated excess particle loading from five along-axis tows. The start time (in Julian days) of each tow was: S6, 151.4; S20, 162.2; S22, 166.1; S23, 166.5; S26, 169.2. Good agreement was found between tows that closely matched in both space and time (that is, S22 and S23). The distance scale corresponds to that of Fig. 1.

by departures of up to 0.1°C from the local θ -S curve and (on casts) by particulate Fe/Al ratios enriched up to 79 times the background value of ~ 1 . Light-scattering observations, however, provided greater sensitivity than temperature in identifying hydrothermal plumes and far greater resolution than discrete chemical samples in describing them. Particle concentrations within the axial valley and off-axis plumes were elevated 2–10 times above the background particle concentration of $\sim 8 \mu\text{g l}^{-1}$ determined from mid-depth water samples. The horizon of maximum particle concentration in the axial valley characteristically occurred 30–120 m.a.b. (Fig. 2a) and was punctuated by localized maxima exceeding $35 \mu\text{g l}^{-1}$ and vertical gradients up to $5 \mu\text{g l}^{-1} \text{ m}^{-1}$. Well-defined plumelike features such as that centred at km 8.5 of tow S20 (Fig. 2a) were rare and restricted to a horizontal dimension of 1–3 km. Intense concentration maxima ($>40 \mu\text{g l}^{-1}$) preferentially occurred in the northern half of the study area and were separated by intervals of 2–3 km; this distribution conforms to the distribution of active vent fields documented by deep-tow photography⁹ and submersible observations¹⁰.

The concentration of particles originating solely from plume emissions was estimated by subtracting the background value of $8 \mu\text{g l}^{-1}$ from all transects and vertically integrating the resulting excess mass loading. These calculations will exceed the true emission loadings by the amount that resuspension of non-hydrothermal sediment contributes to the observed concentrations, but maximum current speeds of only 14 cm s^{-1} (V4) and the prevalence of above-bottom particle maxima suggest that resuspension was weak. Plume loadings calculated at 1-km intervals along five tows show marked spatial and temporal variability (Fig. 2b), consistent with the pattern expected from

discrete vent fields whose emissions are advected by a variable current regime. Temporal changes in discharge rates could also influence the interpretation of the observations.

After documenting the presence of hydrothermal plumes within the axial valley, we conducted eight cross-axis tows to evaluate the likelihood of off-axis dispersion of the particles. The tows were spaced at ~ 2 -km intervals along the valley (Fig. 1); all but the most southerly two found asymmetric plumes of varying intensity apparently originating along the centre or west side of the valley and extending up to, and sometimes over, the west ridge crest. (A particle plume at ridge-crest depths was also detected up to 10 km east of the valley by individual CTD casts.) Particle concentration isopleths along all of these tows roughly paralleled the bathymetry. The longest tow, S25, traced a continuous plume for >8 km west of the axial valley (Fig. 3a). The hydrothermal origin of this feature was confirmed by the continuity of elevated Fe/Al ratios of collected particles westward from the valley (Fig. 3a). Significant maxima at ridge-crest depths in both particle concentration and Fe/Al ratios were also observed on CTDs 20 km and 100 km to the west, suggesting that crestal emissions spread away from the ridge along the isopycnal $\sigma_\theta = 27.72$.

In contrast to these distinct off-axis trends, mean velocities at V4 and V5 during the cruise were weak ($1\text{--}2 \text{ cm s}^{-1}$) and directed northwards roughly parallel to the ridge axis. Mean cross-axis currents were $<5\%$ of along-axis currents within the valley (50 m.a.b. at V4) but increased to 25% 200 m.a.b. at V4 and to 20% at V5. Tidal currents (V4) were dominated by the M2 component, which had a major-axis amplitude of $\sim 4 \text{ cm s}^{-1}$, oriented along the ridge, with an ellipticity of ~ 0.1 .

The presence of a plume several kilometres west of the valley

Fig. 3 *a*, Relative light-scattering isopleths constructed from cross-axis tow S25 and two off-axis CTDs. Plume contours parallel the ridge crest bathymetry out to ~km 4, beyond which the plume concentration maximum spreads along the isopycnal $\sigma_\theta = 27.72$. Locations of moored current meters and sediment traps discussed in the text (●) are shown in relation to the ridge bathymetry. The inset shows particulate Fe/Al ratios from water samples collected on CTDs in the ridge-crest vicinity (Fig. 1) and at 20 and 100 km west. *b*, Vertically-integrated excess particle loading from cross-axis transects S25 and S24 and CTDs 17 and 20. The start time (in Julian days) of each cast was: CTD17, 159.7; CTD20, 163.1; S24, 167.2; S25, 168.3. The west ridge crest is at km 1.8.

in the face of predominantly northward advection suggests that the plume had multiple sources. We speculate that particles from vent fields close to the S25 track caused the within-valley plume, while particles from more southerly vent fields crossed the track several kilometres west (and east) of the ridge crest. The vertically-integrated particle loading along S25 (Fig. 3b) shows a major peak on the western edge of the valley, and two lesser peaks west of the ridge crest that could be indicative of separate, southerly sources. Tow S24, taken 1 day earlier just to the north of S25, shows a similar loading increase, west of the ridge crest, that could have been continuous with the S25 plume (Fig. 3b). The paucity of our coverage, however, means that these results might have other interpretations.

If particle production by the vent fields was approximately steady state during the cruise, and if our off-axis transects were representative of the entire ridge, the off-axis loading decrease must result primarily from settling and/or horizontal dispersion. The contribution of settling can be evaluated from the vertical flux of hydrothermal material. The total particle flux into the sediment traps was $0.11 \pm 0.04 \text{ g m}^{-2} \text{ day}^{-1}$ for 10 two-day samples at V4, and $0.19 \text{ g m}^{-2} \text{ day}^{-1}$ for a single 10-day sample at V5. Elemental analysis indicates that the trapped material was predominantly biogenic and aluminosilicate, with <10% of the total attributable to hydrothermal phases. If a flux of $\leq 0.01 \text{ g m}^{-2} \text{ day}^{-1}$ is thus characteristic of hydrothermal phases in the study area, settling can have only a minor impact on the observed plume loadings. We note, however, that this flux could support the hydrothermal phase accumulation rates of $0.001\text{--}0.004 \text{ g m}^{-2} \text{ day}^{-1}$ found in the vicinity of the Juan de Fuca Ridge¹⁴.

We infer from these observations the following model of hydrothermal plume distributions around the southern Juan de Fuca Ridge. Buoyant vent emissions create a particle distribution that is vertically stratified around above-bottom concentration maxima. Along-axis variability arises because vent fields are not

continuous along the axial valley. Cross-axis tows and CTDs demonstrate that hydrothermal particles are effectively transported off axis, even though the net advective direction is northward, within roughly $\pm 20^\circ$ of the axial strike. We hypothesize that the loss rate of suspended hydrothermal phases by settling is slow enough to enable diffusion to coalesce individual plumes into a laterally uniform far-field hydrothermal cloud at distances of 20–100 km from the ridge crest, analogous to the cloud formed by dissolved tracers such as ^3He (ref. 15) and Mn (ref. 16).

This study has provided an initial description of the distribution of suspended hydrothermal particles; determination of a regional mass-balance between suspended and deposited particles will require quantification of both the percentage of emissions that escapes local deposition and becomes suspended in a plume, and the rate of *in situ* particle-production by slow precipitation of dissolved species within the advecting plume.

We thank H. Milburn and R. Newman for technical assistance in the development of the towed sensor system. This research was supported by the NOAA VENTS Program.

Acetylcholine activates an inward current in single mammalian smooth muscle cells

C. D. Benham, T. B. Bolton & R. J. Lang

Department of Pharmacology and Clinical Pharmacology,
St George's Hospital Medical School, London SW17 0RE, UK

Acetylcholine, the major excitatory neurotransmitter to the smooth muscle of mammalian intestine¹, is known to depolarize smooth muscle cells with an apparent increase in membrane conductance². However, the ionic mechanisms that are triggered by muscarinic receptor activation and underlie this response are poorly understood, due in part to the technical problems associated with the electrophysiological study of smooth muscle³. The muscarinic action of acetylcholine in certain neurones has been shown to involve the switching off of a resting K^+ current (M-current)⁴ and a similar mechanism has recently also been identified in smooth muscle of amphibian stomach⁵. We have now applied the patch-clamp technique⁶ to single smooth muscle cells^{7,8} of rabbit jejunum and find that muscarinic receptor activation switches on a non-selective, voltage-sensitive inward current. In addition, acetylcholine activates and then suppresses spontaneous K^+ current transients, which are probably triggered by rises in intracellular Ca^{2+} in these cells.

Membrane current and voltage recordings were made from enzymatically dispersed single cells isolated from the longitudinal smooth muscle layer of adult rabbit jejunum⁷. These cells were 5–15 μm wide, up to 300 μm long and contracted on application of acetylcholine. Acetylcholine was applied either in the bathing solution or by iontophoresis from a glass micropipette placed about 10 μm from the mid-region of partially contracted cells, chosen to ensure uniform potential during voltage clamp (Fig. 1). Membrane currents and membrane potentials were recorded with a glass pipette in the 'whole-cell' recording configuration⁶.

In normal physiological saline solution, acetylcholine applied iontophoretically or in the bathing solution (0.1–10 μM) evoked contraction, membrane depolarization associated with an increase in membrane conductance (indicated by a reduction in size of hyperpolarizing electrotonic potentials) and action potential discharge (Fig. 1a). Thus, these single cells show similar membrane potential responses to those of cells within intact strips of smooth muscle tissue recorded with other techniques². During voltage-clamp, acetylcholine evoked an inward current at holding potentials between –40 and –80 mV (Figs 1b, 2a,b). This inward current cannot be explained as a decrease of a resting outward K^+ current, as input resistance decreases and there is an increase in current noise indicating that additional channels were being opened rather than already open ones being closed (Fig. 1a, c). To further investigate the mechanism of action of acetylcholine, we applied it to cells in solutions with elevated K^+ concentrations clamped at the K^+ equilibrium potential, E_K , so eliminating any possibility of a contribution from changes in K currents under these conditions. Figure 1c shows a response obtained from a cell bathed in 45 mM K^+ and voltage clamped at E_K (–25 mV). A large inward current was still generated by acetylcholine application, showing that inward current was activated which at this potential could not be due to K^+ ion flow.

Further analysis of the ionic selectivity of this current required the measurement of responses from the same cell at various membrane potentials, and this was made more difficult by the slowness of the response and its decline in size upon repetition. However, by bathing cells in elevated K^+ -containing solutions, we were able to obtain stable recordings for up to 40 min that allowed several responses such as those shown in Fig. 2a to be recorded in the same cell. At E_K (–25 mV) the inward current response was close to its maximum of about 30 pA after about

Fig. 1 Membrane potential and membrane current responses of jejunal smooth muscle cells to acetylcholine (ACh) application. **a**, Membrane potential record from a single cell with a small holding current applied to suppress spontaneous action potential discharge. Current pulses of alternating polarity were injected to evoke electrotonic potentials, and the depolarizing pulses elicited action potentials. ACh (2 s, 50 nA) was applied from an iontophoretic pipette positioned about 10 μm from the mid-region of the cell. This cell had an input resistance of 4.5 G Ω and cell capacitance of 70 pF (calculated from the hyperpolarizing electrotonic potential), which indicates a surface area of 6,700 μm^2 if 10^{-6} F cm^{-2} is assumed for specific membrane capacitance. This gives a space constant at the resting membrane resistance of about 5 mm, which is 60 times greater than the length of the short cable in these single cells. Thus, cells under voltage-clamp will be close to isopotential even with a substantial increase in conductance during acetylcholine application. The cell was bathed in a normal physiological saline solution containing (mM) Na^+ 125; K^+ 6; Ca^{2+} 2.5; Mg^{2+} 1.2; Cl^- 133; HPO_4^- 1.2; HEPES 10; glucose 11. The pipette (intracellular) solution contained (mM) Na^+ 5; K^+ 126; Mg^{2+} 1.2; Cl^- 128; HPO_4^- 1.2; EGTA 0.77; glucose 11; HEPES 10. All solutions were buffered to pH 7.2 and the temperature was 25 °C. **b**, Membrane current response of a cell under voltage-clamp to bath application of acetylcholine when the holding potential (h.p.) was –40 mV. Cell was bathed in same solution as **a**. **c**, Membrane current response of another cell bathed in 45 mM K^+ solution (K^+ replacing Na^+) at the calculated K^+ equilibrium potential (–25 mV). The lower trace shows the same response high-pass filtered at 1 Hz to show the increase in current noise on acetylcholine application. This increase in current noise is most simply explained by the opening and closing of channels activated by acetylcholine responsible for the inward current.

5 s and had a latency of around 500 ms. This current was reduced in amplitude at both more negative and more positive potentials. Figure 2b shows the current needed to clamp the cell at various potentials before and during the effects of acetylcholine application. The two extrapolated lines intersect just positive to 0 mV. This extrapolated E_{rev} does not correspond to the equilibrium potential of any one ion, indicating that the current is carried by a mixture of ions—probably K^+ , Na^+ and/or Ca^{2+} as has been concluded from work on whole smooth muscle tissue^{1,2}. The net agonist-induced current plotted against potential in this elevated K^+ concentration was U-shaped due to deviation from an ohmic conductance at potentials negative to –20 mV (Fig. 2c). Also shown are the averaged responses of 15 cells in normal (6 mM K^+) solution. The shape of the relationship appeared to be similar although shifted to the left, as might be expected from a leftward shift in E_K if K^+ was a permeant ion. Records obtained in this solution in the most interesting range of –30 to 0 mV, where the reversal potential probably lies, were complicated by the appearance of a burst of transient outward currents upon acetylcholine application (see below).

In solutions containing 45 mM K^+ , we had a better estimate

Fig. 2 *a*, Membrane current responses recorded from a single cell under voltage-clamp at five different holding potentials. Responses to 1-s iontophoretic pulses of acetylcholine were evoked at intervals of 8 min. Small horizontal bars indicate zero current level. Note the transient currents that appear as vertical deflections at holding potentials (h.p.) of 0, -10 mV (when they are outward) and -50, -65 mV (when they are inward); they are not seen at E_K (-25 mV). On acetylcholine application their frequency is temporarily increased and they may summate to produce an initial K^+ current that precedes the slower acetylcholine-induced current; after their initial potentiation the transient currents are inhibited for minutes. *b*, Current required to hold this cell at various potentials in the absence and presence of acetylcholine plotted from responses shown in *a*. The acetylcholine-induced current is maximal close to E_K and declines at potentials positive and negative to E_K ; it has an extrapolated reversal potential of about +5 mV. *c*, Net agonist-induced current at various potentials plotted from responses shown in *a* (■), and means of 33 responses from 15 cells in normal physiological saline (▲) $n = 2-7$. *d*, Chord conductance of responses shown in *a* using the extrapolated reversal potential under these conditions of +5 mV. The slope of the conductance curve between -50 and -25 mV gave an e-fold shift per -27 mV.

of E_{rev} at +5 mV (Fig. 2c) and this enabled the chord conductance of the current to be calculated. This showed that the acetylcholine-evoked current increased over the range -70 to -20 mV. The same type of voltage sensitivity, which could produce a regenerative depolarization, is produced by glutamate acting on *N*-methyl-D-aspartate (NMDA) receptors in certain neurones⁹. The non-ohmic properties of the NMDA current have recently been shown to be due to block of the channels at negative potentials by Mg^{2+} ions^{10,11}. We have not observed any effect of removing external Mg^{2+} on responses to acetylcholine, which suggests that the voltage dependence was not due to Mg^{2+} block. When instantaneous hyperpolarizing voltage jumps from -40 to -70 mV were applied at the peak of the acetylcholine response, an inward current was observed that decayed to a steady state with a $t_{1/2}$ of about 5 ms.

Acetylcholine application produced other changes in membrane currents. Spontaneous transient outward currents of varying amplitude, about 50 ms duration and with a frequency of 0.5-3 Hz were observed in cells bathed in elevated K^+ solution with normal calcium concentration and also in cells in normal solution at depolarized potentials, conditions which would tend to cause an increased level of internal calcium. Application of acetylcholine sometimes induced a brief potentiation of these transient outward currents in both frequency and amplitude. This potentiation preceded the onset of the inward current, and was consistently followed by long-lasting inhibition of the transient outward currents (Fig. 2a). These brief currents may represent the activation in response to transient increases in intracellular calcium of Ca^{2+} -activated K^+ channels which we have identified in these cells¹²; the transient currents reversed at the K^+ equilibrium potential (Fig. 2a) were blocked, by external Ba^{2+} ions (2-10 mM) and were not seen if Cs^+ replaced K^+ in the pipette or if the concentration of EGTA in the pipette was raised to 10 mM. These currents were activated by caffeine (5 mM), which is known to release intracellular stores of Ca^{2+} in muscle¹³. Fluctuations in intracellular calcium concentration ($[Ca^{2+}]_i$) that might stimulate such currents have been measured directly in cardiac cells¹⁴, and similar transient potassium currents caused by fluctuations in $[Ca^{2+}]_i$ have been observed in neurones¹⁵.

A biochemical mediator within the cell may be important in triggering the inward current produced by muscarinic receptor activation, as the long latency of this response suggests a rather indirect coupling between receptor and channels. The latency can no longer be dismissed as being due to a long extracellular diffusion pathway, as in our system we know the cells must have clean, naked membranes to obtain gigaohm seals with our recording pipette. (A diffusion distance of 10 μm would induce a nicotinic response at the neuromuscular junction in less than 10 ms¹⁶. A rise in $[Ca^{2+}]_i$ does not seem to be a possible mechanism (as in neurones¹⁷ and the heart¹⁸), because caffeine did not stimulate an inward current.

In conclusion, we have succeeded in dissecting some of the complex membrane events that underlie the excitatory muscarinic action of acetylcholine in mammalian smooth muscle. The major effect of acetylcholine was to stimulate a voltage-dependent inward current that leads to depolarization of the cell and initiates action potential discharge. This current was large at the potassium equilibrium potential and was a non-selective increase in permeability, probably to cations, as has been described for whole smooth muscle tissues^{1,2,19}. In addition, acetylcholine causes a long-lasting inhibition of spontaneous outward current transients, which are probably caused by the transient opening of Ca^{2+} -activated K^+ channels. The two types of channel modulation that we have observed are sufficient to explain the membrane responses of whole tissues of mammalian visceral smooth muscle to acetylcholine.

Inositol 1,4,5-trisphosphate induces calcium release from sarcoplasmic reticulum of skeletal muscle

Pompeo Volpe*†, Giovanni Salvati†, Francesco Di Virgilio†‡ & Tullio Pozzan†

* Centro di Studio per la Biologia e la Fisiopatologia Muscolare del CNR, † Centro di Studio per la Fisiologia dei Mitochondri del CNR and ‡ Istituto di Patologia Generale dell'Università di Padova, via Loredan 16, 35131 Padova, Italy

The sarcoplasmic reticulum of skeletal muscle is a specialized form of endoplasmic reticulum¹ that controls myoplasmic calcium concentration and, therefore, the contraction-relaxation cycle². Ultrastructural studies³ have shown that the sarcoplasmic reticulum is a continuous but heterogeneous membranous network composed of longitudinal tubules that surround myofibrils and terminal cisternae. These cisternae are junctionally associated, via bridging structures called 'feet'⁴, with sarcolemmal invaginations (the transverse tubules) to form the triadic junction⁴. Following transverse tubule depolarization, a signal, transmitted along the triadic junction, triggers Ca^{2+} release from terminal cisternae^{5,6}, but the mechanism of this coupling is still unknown⁷. Inositol 1,4,5-trisphosphate ($\text{Ins}(1,4,5)\text{P}_3$) has recently been shown to mobilize Ca^{2+} from intracellular stores, referable to endoplasmic reticulum, in a variety of cell types (see ref. 8 for review), including smooth muscle cells of the porcine coronary artery⁹ and canine cardiac muscle cells¹⁰. Here we show that $\text{Ins}(1,4,5)\text{P}_3$ (1) releases Ca^{2+} from isolated, purified sarcoplasmic reticulum fractions of rabbit fast-twitch skeletal muscle, the effect being more pronounced on a fraction of terminal cisternae that contains morphologically intact feet structures¹¹; and (2) elicits isometric force development in chemically skinned muscle fibres.

Ca^{2+} uptake by and Ca^{2+} release from isolated sarcoplasmic reticulum (SR) fractions were measured with a Ca^{2+} -sensitive electrode. Figure 1a shows that terminal cisternae (TC) accumulated 43 nmol of Ca^{2+} per mg of protein and then (dashed line) reached a slightly lower steady state¹². Addition of 25 μM $\text{Ins}(1,4,5)\text{P}_3$ (continuous line) promoted Ca^{2+} release, and a new, much lower steady state was attained. Following a biphasic pattern, approximately 50% of the accumulated Ca^{2+} was released within 5 min and then slowly re-accumulated. The effect of $\text{Ins}(1,4,5)\text{P}_3$ was specific since neither inositol 1,4-bisphosphate ($\text{Ins}(1,4)\text{P}_2$) nor inositol 4,5-bisphosphate ($\text{Ins}(4,5)\text{P}_2$) caused Ca^{2+} release from either TC fractions or fractions of longitudinal tubules (LSR), when tested at 25 μM (Table 1).

Figure 1b shows the relationship between the extent of Ca^{2+} release and $\text{Ins}(1,4,5)\text{P}_3$ concentration. Half-maximal stimulation of Ca^{2+} release was obtained at 4–5 μM $\text{Ins}(1,4,5)\text{P}_3$ for both TC and LSR fractions. $\text{Ins}(1,4,5)\text{P}_3$ was more effective on TC than on LSR, where only 20% of the accumulated Ca^{2+} was released. The partial sensitivity of LSR to $\text{Ins}(1,4,5)\text{P}_3$ is due, at least in part, to the contamination of this fraction by about 20% TC vesicles (compare with ref. 11), as indicated by the effect of ruthenium red, an inhibitor of Ca^{2+} release from TC¹³⁻¹⁵ but not from LSR^{15,16} fractions. Ruthenium red at 20 μM almost completely blocked $\text{Ins}(1,4,5)\text{P}_3$ -induced Ca^{2+} release from TC, but produced a decrease of only 50% in release from LSR

Fig. 1 $\text{Ins}(1,4,5)\text{P}_3$ promotes Ca^{2+} release from isolated SR fractions. *a*, After peak Ca^{2+} accumulation, there was a small, basal Ca^{2+} release (dashed line). Addition of 25 μM $\text{Ins}(1,4,5)\text{P}_3$ (continuous line) promoted a large Ca^{2+} release from TC, and a new lower steady state was attained. The rate of Ca^{2+} release induced by $\text{Ins}(1,4,5)\text{P}_3$ (fast phase) could not be determined accurately because of the inherent slow response of the Ca^{2+} electrode. As a lower limit, we calculated a rate of 1 nmol of Ca^{2+} per s per mg of TC protein, that is, three orders of magnitude lower than that estimated *in vivo*³¹ $\text{Ins}(1,4,5)\text{P}_3$ by itself produced only a small increase of medium Ca^{2+} that accounted for about 4% of the effect shown. *b*, A summary of data obtained from several experiments as shown in *a*, using either LSR (O) or TC (●) fractions. The extent of $\text{Ins}(1,4,5)\text{P}_3$ -induced Ca^{2+} release was calculated as the difference between total (+ $\text{Ins}(1,4,5)\text{P}_3$) and basal Ca^{2+} release at steady state, and was expressed as percentage of Ca^{2+} accumulated by the SR. Similar results were obtained using three different SR preparations.

Methods. SR fractions were isolated from rabbit fast-twitch skeletal muscles and purified by differential and density gradient centrifugation^{11,32}. R2 (LSR) and R4 (TC) fractions were resuspended in 0.3 M sucrose, 5 mM imidazole pH 7.4 and stored at -70°C until used. Protein concentration was determined by the Lowry method³³, using bovine serum albumin as a standard. $\text{Ins}(1,4,5)\text{P}_3$ was prepared by incubating human erythrocyte ghosts at 37°C for 15 min with 2 mM CaCl_2 , followed by Dowex-formate column separation, salt removal with 2 M LiCl and three consecutive extractions with ethanol^{24,34}. Ca^{2+} uptake and Ca^{2+} release were continuously monitored with a Ca^{2+} -sensitive electrode (G. Moller, Zurich). The assay was carried out at room temperature ($22-24^\circ\text{C}$) in a medium containing, in a final volume of 4 ml, 20 mM Tris-Cl pH 6.8, 0.1 M KCl, 5 mM MgSO_4 , 2.5 mM ATP, 5 mM $\text{Na}_2\text{-phosphocreatine}$ and 80 μg creatine kinase. Several pulses of 10 nmol CaCl_2 were sequentially added to calibrate the response of the Ca^{2+} electrode, and the reaction was started with either 600 μg of TC or 300 μg of LSR protein, when medium-free Ca^{2+} was 4 μM . LSR and TC fractions accumulated 102 ± 9 and 40 ± 5 nmol of Ca^{2+} per mg of protein, respectively (mean $\pm$ s.d., $n = 5$).

(Table 1). The small ruthenium red-insensitive $\text{Ins}(1,4,5)\text{P}_3$ -induced Ca^{2+} release appears to be a LSR characteristic (Table 1). Thus, our results suggest that $\text{Ins}(1,4,5)\text{P}_3$ acts preferentially on junctional SR (TC) fractions. Interestingly, Berridge and Irvine⁸ have postulated a subspecialization for endoplasmic reticulum of other cell types in which only regions lying close to the plasma membrane might be sensitive to $\text{Ins}(1,4,5)\text{P}_3$.

The ability of $\text{Ins}(1,4,5)\text{P}_3$ to release Ca^{2+} from the SR was further investigated using a chemically skinned fibre preparation¹⁷. Ca^{2+} release from the SR was measured indirectly by monitoring isometric force development¹⁷. Segments of single fibres (average mean diameter 50 μm) were exposed to Ca^{2+} loading solution (free $\text{Ca}^{2+} = 0.40 \mu\text{M}$) for 30 s, so that the SR could accumulate Ca^{2+} , rinsed in EGTA-free solution and then challenged with $\text{Ins}(1,4,5)\text{P}_3$ that elicited transient force development (Fig. 2a). At low $\text{Ins}(1,4,5)\text{P}_3$ concentrations (1 μM , upper trace in Fig. 2a), the time course of force development was biphasic, that is, a slow phase turned into a faster one after approximately 30 s. An S-shaped time course suggests that $\Delta[\text{Ca}^{2+}]/\Delta t$ in the intermyofibrillar space was very small¹⁸ after stimulation. At higher $\text{Ins}(1,4,5)\text{P}_3$ concentrations, (20 μM , lower trace in Fig. 2a), force development was monophasic. These results imply that $\text{Ins}(1,4,5)\text{P}_3$ was able to release Ca^{2+}

from TC, which are the only Ca^{2+} storage compartments of the SR of skeletal muscle fibres^{6,19}. At 20 μM $\text{Ins}(1,4,5)\text{P}_3$, $t_{1/2}$ to peak tension was 3 s and rate of tension rise, normalized against that obtained in the presence of 10 mM caffeine, a drug known to cause Ca^{2+} release from TC of isolated fractions²⁰ and of intact²¹ and skinned²² fibres, was 0.58. The slow rate of force development might be determined by the rate of $\text{Ins}(1,4,5)\text{P}_3$ diffusion throughout the cross-section of the fibre, and by the extent of $\text{Ins}(1,4,5)\text{P}_3$ hydrolysis (see below). Figure 2b shows a plot of relative rate of tension rise versus $\text{Ins}(1,4,5)\text{P}_3$ concentration. Half-maximal rate was obtained at 3 μM . $\text{Ins}(1,4,5)\text{P}_3$ action depended critically on Ca^{2+} loading by the SR of skinned fibres. The effect of 10 μM $\text{Ins}(1,4,5)\text{P}_3$ on the rate of tension rise was decreased by 70% when loading time was reduced from 30 to 15 s or was abolished if the free Ca^{2+} of the loading solution was decreased from 0.4 to 0.16 μM .

As with isolated SR fractions, the ability to release Ca^{2+} appears to be specific for $\text{Ins}(1,4,5)\text{P}_3$, since 20 μM of either $\text{Ins}(1,4)\text{P}_2$ or $\text{Ins}(4,5)\text{P}_2$ had a minimal effect on force development in skinned fibres, that is 3–6% of that obtained with the same amount of $\text{Ins}(1,4,5)\text{P}_3$ (not shown). Furthermore, $\text{Ins}(1,4,5)\text{P}_3$ -induced force development was completely abolished by 20 μM ruthenium red (not shown). Ruthenium red inhibits Ca^{2+} release from the SR of chemically skinned fibres (G.S. and P.V., in preparation) as well as from isolated TC fractions.

The proposed role of $\text{Ins}(1,4,5)\text{P}_3$ as a second messenger for releasing Ca^{2+} from intracellular stores⁸ requires: first, substrates (phosphatidylinositol 4,5-bisphosphate, $\text{PtdIns}(4,5)\text{P}_2$), specific hydrolases ($\text{PtdIns}(4,5)\text{P}_2$ phosphodiesterase or phospholipase C) at the surface membrane level, and inactivating enzymes (inositol trisphosphatase); second, specificity for endoplasmic reticulum receptors; and third, a polyphosphoinositide breakdown rate compatible with cellular response times.

The data reported here are consistent with the possibility that $\text{Ins}(1,4,5)\text{P}_3$ is the specific chemical transmitter in the triadic junction where signal transduction for muscle activation occurs. In fact: (1) $\text{Ins}(1,4,5)\text{P}_3$ -induced Ca^{2+} release was preferentially displayed by TC fractions, which are enriched in junctional SR membranes, and was antagonized by ruthenium red, a blocker of TC Ca^{2+} channels¹³; (2) $\text{Ins}(1,4,5)\text{P}_3$ evoked Ca^{2+} release from TC of skinned muscle fibres; and (3) $\text{Ins}(1,4,5)\text{P}_3$ was preferred over $\text{Ins}(1,4)\text{P}_2$ and $\text{Ins}(4,5)\text{P}_2$. A simplified model for transverse tubule (TT)–TC coupling may be outlined as follows. After TT depolarization, $\text{Ins}(1,4,5)\text{P}_3$ is produced at the myoplasmic leaflet of the TT membrane and released into the triadic junction; $\text{Ins}(1,4,5)\text{P}_3$ -sensitive Ca^{2+} channels, localized in junctional SR (TC) membranes, open and myoplasmic free Ca^{2+} rises. Alternatively, $\text{Ins}(1,4,5)\text{P}_3$ may evoke a small Ca^{2+}

Fig. 2 $\text{Ins}(1,4,5)\text{P}_3$ elicits isometric force development in chemically skinned muscle fibres. *a*, Upper and lower traces show the effect of 1 and 20 μM $\text{Ins}(1,4,5)\text{P}_3$, respectively. *b*, A summary of data from several experiments as shown in *a*. Rate of tension rise, at specified $\text{Ins}(1,4,5)\text{P}_3$ concentration, was normalized against that obtained with 10 mM caffeine. When rates were biphasic, faster rates were considered. Variability was observed in the response to 20 μM $\text{Ins}(1,4,5)\text{P}_3$: 10 fibres were fully responsive, 4 fibres were partially responsive (~20% of the effect shown in *b*) and 3 fibres were not responsive at all. Such differences can be tentatively ascribed to variations in (1) $\text{Ins}(1,4,5)\text{P}_3$ hydrolysis (which should be already low at 0.1 mM free Mg^{2+})^{23,24}; (2) Ca^{2+} loading by the fibres and (3) fibre diameter and relative diffusion times into the fibre. In some experiments, we used $\text{Ins}(1,4,5)\text{P}_3$ derived from ox brain $\text{PtdIns}(4,5)\text{P}_2$ (ref. 30) and results were comparable.

Methods. Rabbit adductor muscle bundles were chemically skinned^{17,35} and stored at -20°C in a solution containing 50% glycerol, 5 mM $\text{K}_2\text{-EGTA}$, 0.17 M K-propionate pH 7.0, 2.5 mM $\text{K}_2\text{-Na}_2\text{-ATP}$, 2.5 mM Mg-propionate and 10 mM imidazole propionate. For isometric force measurements, segments of single fibres were positioned between two clamps, one of them attached to a strain gauge, and stretched to 130% of the slack length³⁵. After 30–45 s in solution R (5 mM $\text{K}_2\text{-EGTA}$, 0.17 M K-propionate , 2.5 mM Mg-propionate , 5 mM $\text{K}_2\text{-Na}_2\text{-ATP}$ and 10 mM imidazole propionate pH 7.0) fibres were allowed to accumulate Ca^{2+} for 30 s in a $p\text{Ca}$ 6.4 loading solution (0.17 M K-propionate , 2.5 mM Mg-propionate , 5 mM $\text{K}_2\text{-Na}_2\text{-ATP}$, 2.5 mM CaCl_2 , 5 mM $\text{K}_2\text{-EGTA}$ and 10 mM imidazole propionate pH 7.0), rinsed for 20–30 s in solution W (solution R without EGTA), and then challenged with $\text{Ins}(1,4,5)\text{P}_3$. Free Mg^{2+} (kept constant at 0.09 mM) and free Ca^{2+} (0.40 μM) were determined using association constants given in Orentlicher *et al.*³⁶ All experiments were carried out at room temperature ($22\text{--}24^\circ\text{C}$) and ionic strength 0.2 M.

efflux which, in turn, triggers a massive Ca^{2+} release by opening TC Ca^{2+} -gated Ca^{2+} channels¹³. The relevance of this model to *in vivo* Ca^{2+} release could not be assessed fully in the skinned fibre preparation because of an experimental constraint that cannot be overcome, that is, exogenous $\text{Ins}(1,4,5)\text{P}_3$ must be added to the bathing solution from where it diffuses into the fibre. Interestingly, $\text{Ins}(1,4,5)\text{P}_3$ triggered Ca^{2+} release from the SR of mechanically skinned frog skeletal muscle fibres²³, and $\text{Ins}(1,4,5)\text{P}_3$ was more effective²³ if its hydrolysis was inhibited by either low free Mg^{2+} (ref. 24) or 2, 3-diphospho-D-glycerate²⁴.

The proposed model is still highly speculative and several crucial questions remain unanswered: does $\text{PtdIns}(4,5)\text{P}_2$ phosphodiesterase exist in TT membranes and, more importantly, does polyphosphoinositide breakdown take place during muscle activation? In this respect we note that Novotny *et al.*²⁵ have shown that K^+ depolarization increased ^{32}P -labelling of phosphatidylinositol in frog sartorius muscles, and that the phosphatidylinositol response is caused by K^+ depolarization and not by the ensuing transient Ca^{2+} release from the SR. Moreover, preliminary data obtained by us indicate that water-soluble inositol phosphates could be extracted from rat diaphragm muscle and that ^3H -*myo*-inositol incorporation into membrane phospholipids increased following a 5-s tetanus. Finally, in frog sartorius and semitendinosus muscles, a short-pulse tetanus followed by rapid freezing²⁶ increased the level of phosphatidylinositol, $\text{Ins}(4,5)\text{P}_2$ and $\text{Ins}(1,4,5)\text{P}_3$ to levels three to four times those in controls (J. Vergava and R. Y. Tsien, personal communication). Taken together, these observations suggest that

Table 1 Effect of ruthenium red on $\text{Ins}(1,4,5)\text{P}_3$ -induced Ca^{2+} release from isolated SR fractions, and effect of $\text{Ins}(1,4)\text{P}_2$ and $\text{Ins}(4,5)\text{P}_2$

Additions	Extent of Ca^{2+} release (% of Ca^{2+} accumulated)	
	LSR	TC
$\text{Ins}(1,4,5)\text{P}_3$ (25 μM)	17	47
$\text{Ins}(1,4,5)\text{P}_3$ (25 μM) plus ruthenium red (20 μM)	7	8
$\text{Ins}(1,4)\text{P}_2$ (25 μM)	2	1
$\text{Ins}(4,5)\text{P}_2$ (25 μM)	3	1

Ca^{2+} uptake and Ca^{2+} release were measured as described in Fig. 1 legend. $\text{Ins}(1,4)\text{P}_2$ and $\text{Ins}(4,5)\text{P}_2$ were prepared by alkaline hydrolysis of ox brain $\text{PtdIns}(4,5)\text{P}_2$ (ref. 30). With no additions there was a basal Ca^{2+} release that corresponded to the slightly lower steady state attained after peak Ca^{2+} accumulation (compare Fig. 1a, dashed line), and accounted for approximately 4% and 8% of the Ca^{2+} accumulated in LSR and TC fractions, respectively. The extent of $\text{Ins}(1,4,5)\text{P}_3$ induced Ca^{2+} release was calculated as the difference between total and basal Ca^{2+} release (see Fig. 1). Data are from a typical experiment in which duplicate determinations were performed.

polyphosphoinositide metabolism may be causally related to muscle activation.

Another fundamental question is whether the phosphoinositide breakdown rate is fast enough (in the millisecond range) to exert a physiological role in skeletal muscle contraction. This question was not directly addressed. However, the recent findings^{27,28} that $\text{PtdIns}(4,5)\text{P}_2$ breakdown is involved in phototransduction, a quite complex and rapid event²⁹, encourage us not to rule out *a priori* such a mechanism for muscle activation.

We thank Dr R. F. Irvine for the gift of $\text{Ins}(1,4)\text{P}_2$, $\text{Ins}(4,5)\text{P}_2$ and a sample of specially purified $\text{Ins}(1,4,5)\text{P}_3$, and Dr S. Treves for critically reading the manuscript.

Mapping of general anaesthetic target sites provides a molecular basis for cutoff effects

N. P. Franks & W. R. Lieb

Biophysics Section, Blackett Laboratory, Imperial College of Science and Technology, Prince Consort Road, London SW7 2BZ, UK

A longstanding and unresolved problem in general anaesthesia is the so-called 'cutoff' effect; as one ascends a homologous series of anaesthetic agents, the potencies progressively increase with anaesthetic size but then, rather suddenly, anaesthetic potency disappears^{1–5}. Curiously, this cutoff in potency occurs at very different points in different series. Various explanations have been offered^{5,6}, usually based on the notion that lipid bilayers are the primary target sites in general anaesthesia^{3,4,7}. However, accumulating evidence now suggests that proteins are the primary sites of action^{8–14}. Here we demonstrate cutoff effects for the anaesthetic inhibition of a soluble protein (firefly luciferase) which mirror those found for general anaesthesia, and we describe how the molecular architecture of the binding site accounts for the different cutoffs in the different homologous series. We show that this

Fig. 1 Inhibition constants K_i for the homologous series of *n*-alcohols and *n*-alkanes acting on the enzyme luciferase. Firefly luciferase was purified, its activity assayed and the inhibition constants for competition with the natural substrate luciferin determined as described previously¹⁴. Standard errors in the K_i values were $\leq 20\%$. As before, the data were analysed using a simple binding model¹⁴ in which *N* anaesthetic molecules bind to the enzyme with equal affinities but only one molecule is sufficient to cause inhibition. We find that the break between *N* = 2 and *N* = 1 occurs for the alcohols between *C*₇ and *C*₈. For the alkanes, we confirmed that this break occurs between *C*₆ and *C*₁₀. However, the low activities of the intervening members meant that the exact point could not be ascertained; we took it as being the same as for the alcohols. For the largest molecules with *N* = 2, it seems likely that the two molecules bind with different affinities, although our data were not sufficiently precise to detect this. In such cases, the K_i values we have determined represent weighted averages. The alcohols *C*₁₁–*C*₁₆ were added as ethanolic solutions, such that the final ethanol concentration never exceeded 5% of the K_i for ethanol; the controls nonetheless contained the appropriate concentration of ethanol. Solutions containing the gaseous alkanes *C*₃ and *C*₄ were prepared by bubbling the gases through scintered glass, results obtained after 1 day were identical to those obtained after 2 days of bubbling. The final concentrations were calculated using the mole fraction solubilities given in ref. 18. Saturated solutions of alkanes *C*₅–*C*₁₃ were prepared by prolonged and vigorous shaking with small (~20 ml) volumes of buffer. In addition, alkanes *C*₈–*C*₁₄ were added as ethanolic solutions such that their final concentrations were only about five times in excess of their saturated solutions. Results obtained using these two methods gave excellent agreement. Values for the saturated aqueous solutions of these alkanes were calculated using the straight line relationship shown in Fig. 2b. For each anaesthetic, the concentration of enzyme was always kept well below the lowest concentration of anaesthetic used. The alcohols and alkanes were the purest grades available from Sigma or BDH.

behaviour is a natural consequence of anaesthetics binding to an amphiphilic protein pocket of circumscribed dimensions. When general anaesthetic target sites in animals and the luciferase protein are mapped out using the fine details of the potency data, remarkable similarities are revealed. Our results thus suggest that the target sites in general anaesthesia are amphiphilic pockets on proteins.

The best-characterized examples of homologous series which display cutoffs in anaesthetic potency are the *n*-alcohols and *n*-alkanes. General anaesthetic activity disappears at different points in these two series; the alcohols^{1,4} cut off at about *C*₁₃ while the alkanes^{2,5} cut off between *C*₆ and *C*₁₀, the exact point being species-dependent. To elucidate the molecular basis for these observations, we have determined the inhibition constants for homologous series of both alcohols and alkanes acting on a pure soluble protein. This protein, firefly luciferase, is competitively inhibited by a wide range of general anaesthetics at concentrations which are essentially identical to those which produce general anaesthesia in animals¹⁴.

The inhibition constants K_i for the homologous series of

Fig. 2 The cutoff effect for the homologous series of *n*-alcohols (a) and *n*-alkanes (b). The ED_{50} values are the concentrations of anaesthetics which inhibited luciferase activity by 50% when the concentration of the substrate luciferin was equal to the K_m of the uninhibited enzyme ($14 \mu M$). Standard errors in the ED_{50} values were $\leq 20\%$. The c_{sat} values are the maximum possible aqueous concentrations (the solubilities) of the anaesthetics. When it was not possible to achieve 50% inhibition experimentally, ED_{50} values were estimated by extrapolation from the maximum attainable inhibitions. The c_{sat} values for the alcohols and alkanes are those compiled in ref. 19. The c_{sat} straight lines are drawn according to the equations given in ref. 19; for the alkanes we have assumed¹⁹ that the line can be extrapolated to C_{14} . Arrows indicate the positions of the abrupt cutoffs in potency.

n-alcohols and *n*-alkanes acting on firefly luciferase are plotted against the number of carbon atoms in Fig. 1. The two curves display some expected but also some surprising features. As might be expected for binding to a hydrophobic pocket, the alkanes bind more tightly than their corresponding alcohols, and the addition of a hydrophobic methylene group ($-\text{CH}_2-$) to either type of molecule tends to increase the binding affinity (that is, to reduce K_i). Interestingly, however, the alkanes only bind 5–50 times more tightly than their corresponding alcohols, very much less than the 10,000-fold factor for partitioning between water and a purely hydrophobic solvent such as hexadecane¹⁵. Evidently, the anaesthetic-binding site on luciferase behaves as if it is amphiphilic, containing polar as well as apolar parts. This might be expected of a binding site which presumably extends to the water/protein surface. What is more surprising is that there are two regions in each curve of Fig. 1, at about C_6 and after about C_{12} , where the K_i values level off. In other words, there are two regions in which making an anaesthetic molecule larger and more hydrophobic does not change the free energy of binding.

What molecular interpretation can be placed on these results? We have shown previously¹⁴ that the anaesthetic-binding site on luciferase has a volume roughly equal to that of two hexanol molecules and that for agents larger than heptanol only a single molecule can be accommodated. Thus, at around C_6 , when two molecules bind, the site is becoming fully occupied, so that additional CH_2 groups can no longer bind within the pocket but must remain in water, where they can make little or no contribution to the overall binding energy. The K_i curves therefore tend to level off in this region. Between C_8 and C_{12} , where only one molecule binds, additional CH_2 groups are no longer forced into a polar environment and thus contribute strongly to binding. After C_{12} , a single molecule is now large enough to fill the binding site so that additional CH_2 groups remain in water and the K_i curves level off once again. An alternative explanation for the levelling off at about C_6 is that the hydrocarbon chains encounter packing constraints or even a polar region near the bottom of the pocket, so that CH_2 groups in this region bind weakly. (Such a polar region has previously been postulated¹⁶ to account for the relatively weak binding of hydrocarbons to bovine serum albumin.) Although the details of the molecular interpretation must await future work, the levelling-off of the K_i curves can be accounted for by the anaesthetics binding to

Fig. 3 Corresponding molecular features in the target sites in general anaesthesia and in the anaesthetic-binding pocket on the luciferase protein. The apparent changes in binding energy for a methylene group binding to luciferase (top) and target sites for general anaesthesia (bottom) are plotted as a function of chain length (n). Note the different scales in the vertical direction. Each point was calculated using the difference in thermodynamic free energy, $\Delta\Delta G^\ominus = -RT \ln[(ED_{50})_n/(ED_{50})_{n+1}]$ and alcohol ED_{50} values. The luciferase ED_{50} values are those plotted in Fig. 2a while those for general anaesthesia in animals (tadpoles) are taken from Tables 5 ($n = 1-8$) and 4 ($n = 9-12$) of ref. 20. True binding energies for animal target sites can only be calculated using inhibition constants which are, of course, unknown. So that a fair comparison between the data for general anaesthesia and luciferase inhibition could be made, we have used ED_{50} values throughout. The cross-hatched areas represent regions where methylene (CH_2) groups bind relatively weakly. A molecular interpretation of these features is given in the text.

an amphiphilic pocket of circumscribed dimensions.

To make a direct comparison with known ED_{50} concentrations for general anaesthesia, we determined luciferase ED_{50} concentrations for all of the above agents. (An ED_{50} concentration is one which produces a 50% effect, either anaesthetizing 50% of a population of animals or reducing luciferase activity by 50%.) Since alcohols larger than C_{11} all bind to the protein with roughly equal affinities (see Fig. 1), it might be expected that all of these large molecules would be equally effective at inhibiting enzyme activity. However, while C_{12} , for example, is among the most potent alcohols, we found that C_{16} was not an effective inhibitor. The resolution of this paradox is clear from the data shown in Fig. 2a, where we have plotted alcohol ED_{50} concentrations together with the corresponding maximum aqueous solubilities (c_{sat}). It can be seen that C_{16} is ineffective simply because its maximum achievable aqueous concentration lies well below that necessary to halve the enzyme activity.

Because of the similarities between the alkane and alcohol K_i curves in Fig. 1, one might suppose that the ED_{50} cutoff points for the two series would occur at similar places. However, as observed for general anaesthesia, we found that the alkanes cut off much earlier. The reason for this cutoff is clear from the data in Fig. 2b: the c_{sat} line intercepts the alkane ED_{50} curve between C_6 and C_7 . After C_8 , the site is occupied by only a single molecule and binding again increases such that C_{10} and C_{11} become active, but then, once more, the finite size of the pocket comes into play. (Although this recovery of activity has not, to our knowledge, been looked for in animals, it might well be peculiar to luciferase.)

Thus, for inhibition of luciferase activity, alcohol and alkane cutoffs appear at very different points. The alcohol cutoff at C_{16} is a consequence of the levelling-off of the ED_{50} curve (Fig. 2a) beyond about C_{12} , a result of the circumscribed dimensions of the binding pocket. The alkane cutoff at C_7 , on the other hand, results from the unexpected levelling-off of the ED_{50} curve (Fig. 2b) at about C_6 . In practical terms, the cutoffs occur not because

the anaesthetic molecules bind weakly to the protein but because the maximum aqueous solubilities of the inactive agents lie below the concentrations needed to half-inhibit activity. Our observations provide a plausible basis for interpreting cutoffs in anaesthetic potencies in animals. For tadpoles^{1,4}, the alcohol cutoff occurs slightly earlier (at C_{13} instead of C_{16}), and this may reflect a somewhat smaller volume for general anaesthetic target sites in animals. The alkane cutoffs for different animals^{2,5} occur between C_6 and C_{10} , similar to our value of C_7 .

In lipid theories, alcohol⁴ and alkane⁷ cutoffs have been accounted for in terms of an abrupt decrease in absorption into lipid bilayers. Very recently, however, it has been shown¹⁷ that partition coefficients for *n*-alkyltrimethylammonium ions continue to increase, at least up to C_{18} , with no suggestion of a sudden cutoff in absorption. It seems unlikely, therefore, that potency cutoffs in other amphiphiles, such as the *n*-alcohols, can be explained in terms of bilayer solubility.

Finally, in Fig. 3 we have used alcohol ED_{50} data to make a direct comparison between anaesthetics binding to the luciferase protein and to the target sites involved in general anaesthesia, by plotting the apparent changes in CH_2 binding energies as the alcohol molecule increases in length. The cross-hatched areas indicate those regions on the luciferase and central nervous system target sites where CH_2 groups bind relatively weakly. The remarkable similarity between the data for general anaesthesia and for inhibition of the protein luciferase suggests that corresponding molecular features may be present in the target

sites for general anaesthesia in animals.

Although these target sites in animals have yet to be identified, a pocket of circumscribed dimensions and amphiphilic nature might be expected for a protein site which must selectively bind and orient relatively apolar ligands containing at least one polar group.

We thank Dr E. B. Smith and Professor D. M. Blow for stimulating discussions and the latter for helpful comments on the manuscript. This research was supported by grants from the MRC and the BOC Group, Inc.

Tissue-specific modulation of a set of related cell surface antigens in *Drosophila*

Michael Wilcox & Maria Leptin

Medical Research Council Laboratory of Molecular Biology,
Hills Road, Cambridge CB2 2QH, UK

To be integrated correctly into the developing organism, cells need to interact with an environment that includes neighbouring cells, the extracellular matrix and soluble factors. These interactions probably require specific recognition events mediated by cell-surface molecules, and evidence has accumulated for the presence of such molecules in several organisms (see, for example, refs 1–6). In *Drosophila*, a family of cell-surface glycoprotein complexes, the position-specific (PS) antigens, may be involved in such processes^{7–11}. PS antigens show spatially restricted distributions on imaginal disks that vary during development; their expression on any particular cell correlates with the position of that cell in the developing disk epithelium rather than with its ultimate differentiation. In contrast to the situation in disks, however, immunofluorescence revealed few regional restrictions of PS-antigen expression on other larval tissues^{7,11}. If the PS antigens have a general role in morphogenesis, then widespread regional variation in their distributions might be expected. We now report that, by using polyacrylamide gel electrophoresis (PAGE), a technique that gives higher resolution than immunofluorescence, we detect an increase in both the concentration and the diversity of the complexes during embryogenesis, beginning at gastrulation. Further, each larval and adult tissue examined carries its own characteristic set of complexes. This tissue- and region-specific diversity is achieved by combining different members of a set of related components with a glycoprotein common to all the complexes.

Monoclonal antibodies against the PS1 and PS2 antigens were defined by their preferential binding to cells of the dorsal and ventral compartments, respectively, of the mature wing imaginal disk^{7,8}. The antibodies precipitate different but related complexes of glycoproteins from disk lysates (refs 8, 9; lanes *a* in Fig. 1). Each antibody recognizes components unique to its own complex: glycoprotein 116 (gp116) and gp120 in the case of

PS1 antibodies; gp125 for the PS2 antibodies⁹. A third class of antibodies, PS3, recognize determinants on a gp110 component common to the complexes. PS3 antibodies thus precipitate both the PS1 and PS2 complexes together with at least one further complex containing a gp92 doublet.

To investigate the expression of the antigens on tissues other than imaginal disk, we analysed the composition of embryonic antigens at different stages of development (see Fig. 1 legend for a description of the timing of the main events of embryogenesis) and on different larval and adult tissues to determine whether we could detect variations or restricted distributions not revealed by immunofluorescence staining. Lysates of embryos and of first (24 and 28 h)- and second (52 h)-instar larvae were extracted sequentially, first with PS1, then with PS2 and finally with PS3 antibodies (see Fig. 1 legend) and the antigen components were separated by SDS-PAGE. The main findings, shown in Fig. 1, can be summarized as follows.

(1) The PS complexes are present only at low concentrations until after the onset of gastrulation (which begins ~3.5 h after egg laying, shortly after the formation of the cellular blastoderm). In Fig. 1, only the 1 h and 4 h time points are shown but sampling at other times within this period confirms the observation. From about 4 to 6 h, all PS antigens show a dramatic increase of both amount and complexity.

(2) PS1 and PS2 antibodies extract discrete subsets of the total PS complexes at each stage, leaving behind others which can be extracted subsequently by PS3 antibodies.

(3) Different components appear and reach their maximum levels at different times and several appear only transiently or show fluctuations in their level, for example, the PS1 component of relative molecular mass (M_r) 120,000 (120K), or the PS3 doublet at 92K.

(4) Several components found in embryonic PS antigens do not occur in the disk antigens (lanes *a* of Fig. 1). Thus, each antibody extracts different complexes from different lysates. Moreover, the large number of components often seen in the antigen extracted from embryos by any given antibody suggests that each antibody may be precipitating several different complexes, each expressing a molecule carrying the determinant recognized by that antibody, but containing different components attached to it. Extrapolating from what we know of the spatially restricted distribution of PS antigens on imaginal disks, it seemed likely that the additional complexes in the embryo

Fig. 1 Embryonic and early larval PS antigens. Embryos or larvae of the ages shown were lysed, the lysates extracted in turn with PS1, PS2 and finally PS3 antibodies, and the PS-antigen components resolved by SDS-PAGE. Preliminary experiments showed that the PS1 and PS2 antibody levels were sufficient to remove all antigens recognized by those antibodies. The overall pattern of components and the timing of their appearance is reproducible from experiment to experiment. Lanes *a* show, for comparison, the components of PS1, PS2 and PS3 antigens extracted sequentially from an imaginal disk lysate. The band indicated by an arrowhead at ~100K is a breakdown product of gp110 (ref. 9).

Methods. Eggs were collected from *Drosophila melanogaster* flies (Oregon R strain) over 1-h laying periods, dechorionated and fractured by sonication at the times shown (=time of development $\pm$ 30 min), and proteins were solubilized in 10 vol. of a non-ionic detergent buffer containing 20 mM Tris-HCl pH 8.1, 100 mM NaCl, 1 mM each of $MgCl_2$ and $CaCl_2$, 0.2% each of Nonidet-P40 and Triton X-100, 1% kallikrein inactivator and 1 mM phenylmethylsulphonyl fluoride. Equal volumes (50 μ l) of packed embryos or larvae were used at each time point. Each lysate was extracted in turn with PS1, then PS2 and finally PS3 antibodies attached to Affi-Gel 10 (10- μ l beads in each case). After washing, antigens were eluted from the antibody support columns with 10 μ l sample buffer (125 mM Tris-HCl pH 6.5, 2% SDS, 10% glycerol), reduced by addition of 2-mercaptoethanol to 5% v/v and components resolved by SDS-PAGE on thin (0.75 mm) 8% gels. The components are all glycoproteins and were visualized by the procedure of Hawkes¹³; nitrocellulose (Western) blots¹⁴ from gels are incubated successively in concanavalin A (Con A) and horseradish peroxidase (HRP), and HRP activity is then detected in a staining reaction. M_s were determined using 29–205K protein markers (Sigma). All procedures have been described previously^{8,9}, as has the isolation of the antibodies. Each PS antibody class contains several independently isolated monoclonal antibodies with identical specificities^{8,9}. *D. melanogaster* embryogenesis lasts for ~22 h at 25°C. The timing of some of the major events is as follows (for review see ref. 12): the cellular blastoderm forms at 2.5–3 h after egg laying, gastrulation begins at 3.5 h, morphologically visible segmentation at ~7 h. Most tissue rudiments become visible between 3 and 10 h and organogenesis continues until shortly before the first-instar larva hatches at 22 h. A moult 24 h later marks the beginning of the second larval instar, which lasts until the second moult at ~72 h after egg laying. The third larval stage ends at 120 h, when the animal pupates and begins metamorphosis.

Fig. 2 PS antigens from larval and adult tissues. Lanes *a–i*, total PS antigens extracted by PS3 antibodies. Subsequent extraction of the lysates with PS1 and PS2 antibodies yielded no further antigens, showing that all complexes contained the common gp110 component recognized by PS3 antibodies. Lanes 1–3 of *l–p* are antigens extracted from lysates by PS1, PS2 and PS3 antibodies in sequence (see Fig. 1 legend). Tissues: *a* and *p*, larval gut; *b*, adult gut; *c*, adult testis; *d* and *m*, larval salivary gland; *e* and *n*, larval brain; *f* and *o*, adult ovary (anterior half); *g*, oocytes; *h*, larval fat body; *i*, larval cuticle (contains epidermis plus attached musculature); *j* and *k*, imaginal disk with and without larval gut lysate, respectively (see below); *l*, larval head (contains most imaginal disks together with larval foregut, brain and some epidermis). In all these antigens, the band in the region of 110K (and often one at ~100K) is recognized by the monoclonal antibody DX4C8 (an antibody that binds to disk antigen gp110 and its 100K breakdown product on Western blots, but not on cells or in solution⁹; data not shown).

Methods. Tissues were dissected out of mature third-instar larvae or young adults of the *D. melanogaster* Barton strain (very similar results were obtained using tissues from Oregon R or Canton S animals), lysed by sonication in non-ionic detergent buffer (see Fig. 1 legend) and antigens extracted by the Affi-Gel 10-bound PS antibodies described above. Equivalent volumes (~50 μ l) of packed tissue were used in each case (this volume required variable numbers of organs: 75 pairs of larval salivary glands and 40 adult testes, for example). Antigen components were resolved by SDS-PAGE, then (with the exception of lanes *j* and *k*) transferred to nitrocellulose and visualized with Con A/HRP (see Fig. 1 legend). *j*, *k*, PS3 antigens were extracted from a lysate of ³⁵S-methionine-labelled imaginal disks¹⁵ after incubation for 2 h at 24°C either alone (*j*) or with the lysate from 50 μ l larval gut tissue (*k*) (in another experiment a similar antigen pattern was obtained after incubation with intact extirpated larval gut). ³⁵S-labelled products were visualized by fluorography¹⁶.

Fig. 3 Two-dimensional non-reducing/reducing SDS-PAGE of late embryo PS antigens. Components of total PS antigen extracted from a lysate of 18-h embryos were first fractionated by non-reducing SDS-PAGE on a thin (0.75 mm) 8% gel (*a*). Note that all PS components have moved away from the 110–120K region, some to higher, others to lower apparent M_r s. A lane identical to that shown in *a* was cut out of the gel, treated for 1 h at room temperature with sample buffer containing 5% 2-mercaptoethanol, then placed on top of a second, slightly thicker (0.9 mm) 8% gel and the reduced proteins re-electrophoresed (*b*). (For details of this procedure see ref. 9.) Products were transferred to nitrocellulose and visualized by Con A/HRP staining. Gp110, which migrates more rapidly in the non-reducing dimension, lies above the diagonal (solid line) of the gel; three components can be resolved in this region (all of which are recognized by antibody DX4C8). Several components of higher M_r were retarded similarly in the first dimension (by ~15–20K) and so, in the two-dimensional gel, all lie below the diagonal on a line that also extrapolates to the origin (broken lines). This behaviour is reminiscent of that of gp116, 120 and 125 of the disk antigens, which contain similar polypeptides⁹. The gp92 doublet glycoproteins, which run identically in each dimension, lie on the diagonal.

might also be regionalized, perhaps localized to entire organs and tissues.

To investigate this possibility, we analysed antigens extracted by PS antibodies from lysates of several larval and adult tissues. Figure 2 shows the SDS gel patterns of total PS antigens (precipitated by PS3 antibodies). As expected, the complexes precipitated by the same antibodies from different tissues differ in their composition, with only the common gp110 occurring in all the antigens. These differences were highlighted in experiments in which tissue lysates were sequentially extracted with PS1, PS2 and PS3 antibodies. For example, larval brain (Fig. 2*n*, lanes 1–3) exhibits only low levels of an antigen that is almost exclusively PS2; in particular, little or no PS1 antigen is detectable, in agreement with immunofluorescence staining results¹¹. In the adult ovary (Fig. 2*o*, lanes 1–3), the population of antigens is composed almost entirely of the PS1 and PS2 subsets, while in the larval gut (Fig. 2*p*, lanes 1–3) complexes recognized only by PS3 antibodies predominate.

It is critical to exclude the possibility that this heterogeneity is an artefact; the reproducibility of the patterns is strong evidence against this. Furthermore, qualitatively identical patterns were obtained with tissues from a number of different fly strains (data not shown). Protease inhibitors were included in all preparations to minimize any effect of a differential occurrence of proteases in different tissues and several experiments were carried out to rule out this possible cause of artefacts. Gut PS antigens contain mainly components of low M_r , which might be candidates for degradation products, and the gut is most likely to contain proteolytic enzymes. Therefore, we incubated ³⁵S-methionine-labelled imaginal disk lysates with gut extracts or intact extirpated gut, before extraction with PS3 antibody. The ³⁵S-labelled PS3 antigen from this preparation was identical to that extracted from control lysates (Fig. 2*j*, *k*). Thus, we

could find no evidence of proteolytic or indeed any other modifying activity and conclude that the differences in the SDS gel patterns between different tissues represent differences in the composition of the complexes. In summary, it seems highly likely that the complex embryonic patterns we have described represent the sum of the different complexes found on the various organs and tissues present.

How are the PS antigens on the various organs, tissues and regions of the organism related? The main characteristics of the antigens, their ubiquity and heterogeneity, are reflected in the form of the complexes: each consists of a characteristic set of variable components together with one component, gp110, common to all of them. The fact that complexes of such different composition, for example, those from salivary gland and adult ovary (lanes 2 of *m*, *o* in Fig. 2), are precipitated by the same antibody, shows that at least some of the variable components are related. All these components (except gp92) migrate abnormally on two-dimensional non-reducing/reducing gels; they all appear on a single line extrapolating back to the origin but running below the gel diagonal. For example, in the case of the total PS antigens from 18-h embryos, six components ranging from 112K to ~140K lie on this line below the diagonal (Fig. 3*b*). The high- M_r components (>110K) of antigens isolated at other stages of development behave similarly (data not shown). Interestingly, the variable components of the disk antigens (gp116–125) show the same anomalous behaviour⁹, and partial proteolysis studies have indicated that these components contain similar polypeptides⁹ (while gp92 and gp110 are not related either to each other or to the other components). It seems likely, therefore, that at least some of the variable components of the embryonic and larval antigen complexes are related both to the variable components of the disk complexes and to one another. These variable components may be products of related genes or of one or a small number of common precursors (transcripts or polypeptides), which are modified according to position and time to give rise to the different tissue-specific components. Preliminary deglycosylation studies suggest that the variations do not stem from differential *N*-glycosylation (M.L. & M.W., unpublished observations).

The relatively indiscriminate expression of PS antigens on the majority of *Drosophila* tissues, as detected by immunofluorescence staining, turns out therefore to be only a superficial view of a more complicated picture. At the finer level of analysis used here, temporal and spatial differences in the composition and distribution of the PS antigens become apparent, and we begin to resolve the heterogeneity of the antigens and their specificity for organs and tissues. In effect, the network of position-specific antigens provides different tissues and regions of the organism with characteristic signatures distinguishing them from their surrounding tissues. It remains to be shown whether and how these signatures are used in the organization of the developing fly; the notion that they are in fact used rests largely on the correlation of the temporal and spatial changes of antigen expression with defined morphogenetic events. The restricted distributions of the antigens on imaginal disks and the changes in expression during development have been discussed previously^{7,8,10,11}. We now know also that the first appearance of the antigens during embryogenesis correlates closely with the onset of morphogenetic processes at gastrulation and that PS-antigen complexity increases dramatically during the ensuing hours when the regional organization of the embryo and the subsequent organogenesis are occurring. Our contention that this complexity results from the summing of the components of different tissue- and region-specific complexes first expressed in these early stages, is supported by the tissue-, organ- and region-specific antigen distributions found later in development.

While a role for the PS antigens in specific cell recognition is attractive, the known properties of the molecules may well be consistent with several other possible functions. The use of monoclonal antibodies specific for isolated variable components should help to elucidate the relationships between the antigens, and the location of their genes and subsequent exploitation of

Drosophila genetics should lead to the isolation of mutants that will allow us to establish the function of the antigens.

We thank Richard Smith for technical help, Danny L. Brower for the PS2 antibody (CF2C7) and Nick Brown and many of our colleagues for criticism of the manuscript. M.L. is the recipient of an EMBO long-term fellowship.

Specific targeting of cytotoxic T cells by anti-T3 linked to anti-target cell antibody

Pilar Perez, Robert W. Hoffman, Stephen Shaw, Jeffrey A. Bluestone & David M. Segal*

Immunology Branch, National Cancer Institute, Bethesda, Maryland 20205, USA

The specificity of cytotoxic T lymphocytes (T_c) cells is conferred by an antigen-specific receptor, T_i , which in humans is physically associated with an invariant cell-surface glycoprotein, T3 (refs. 1-3). Monoclonal antibodies specific for either T3 and T_i are able to elicit a variety of T-cell responses such as lymphokine production, mitogenesis and cytotoxicity¹⁻¹¹. For example, human T_c cells lyse anti-T3-expressing hybridoma cells, but not cells of other specificity, presumably because anti-T3 on the hybridoma cells binds to T3 on the T_c cells and triggers lysis¹². Here, we have adapted approaches used in a different cytotoxic effector system, antibody-dependent cellular cytotoxicity (ADCC), to alter the specificity of T_c cell. Studies of ADCC¹³ showed that heteroaggregates containing anti-Fc receptor (Fc γ R) antibody cross-linked to a second antibody bind to Fc γ R on ADCC effectors and cause them to kill target cells bearing antigen recognized by the second antibody. The present studies use anti-T3-containing heteroaggregates to re-target human T_c cells to cells for which we have appropriate antibodies, including xenogeneic tumour cells and chicken erythrocytes. These results extend previous observations on the role of T3 in triggering cytotoxicity and suggest that effector cell re-targeting could be used for *in vivo* treatment of neoplasms and other pathogens that express distinctive surface antigens.

Four different human anti-HLA-DPw2 (SB2) cytotoxic T-cell clones, 8.2, 8.4, 8.5 and 8.9 (ref. 14), were used in this study. All four express the T3 and T4 antigens and target-cell lysis mediated by three of the clones (8.4 being the exception) is inhibited by anti-T3 antibody¹⁴. Clones 8.9 and 8.5 were negative for Fc γ R (as determined by flow cytometry¹⁵) and therefore cannot mediate ADCC (clones 8.2 and 8.4 were not tested).

Fig. 1 SDS-polyacrylamide gel electrophoresis of cross-linked antibodies. Lanes 1-4, non-reduced; lanes 5-8, reduced. Lanes 1, 5, OKT3 (anti-T3); lanes 2, 6, 36-7-5 (anti- K^k); lanes 3, 7, OKT3 cross-linked to 36-7-5 (anti-T3 $\times$ anti- K^k), heavier fraction containing mainly trimers and larger oligomers; lanes 4, 8, lighter fraction of cross-linked material, containing mainly dimers and trimers. The cross-linked material reduces to light and heavy chains because a reducible cross-linking reagent was used in their preparation. Note that the cross-linked preparations contain light chains from both antibodies, as expected. Lane S, standards: IgG (relative molecular mass (M_r) 150,000), bovine serum albumin (68,000), ovalbumin (45,000), chymotrypsinogen (25,000) and cytochrome c (12,500).

Methods. OKT3 (Ortho) and 36-7-5²⁰ antibodies were purified from ascites by ion-exchange chromatography and gel filtration²¹. Each protein (5 mg) was incubated with a threefold molar excess of N-succinimidyl-3-(2-pyridyldithiol) propionate (Pharmacia). OKT3 was then reduced and coupled to 36-7-5 as described previously¹³. The hetero-cross-linked antibodies were eluted on a 1.6 $\times$ 90-cm Ultrogel AcA 22 (LKB) column, fractions taken at relative elution volume $K_d = 0.08-0.33$ (heavy fraction) and 0.38-0.54 (lighter fraction). Monomeric IgG elutes at (K_d) 0.63-0.71. Samples were concentrated with a CX10 immiscible membrane (Millipore), and aliquots were denatured and run on a 2-16% gradient slab gel (Pharmacia). Other antibodies used were affinity-purified rabbit anti-DNP antibodies²² and anti-T4 monoclonal antibody^{1,3} (Ortho) purified as described above. In cross-linking anti-T3 to anti-DNP, an eightfold molar excess of SPDP to each antibody was used. This gave larger heteroaggregates than the threefold excess used in the other combinations, but also partially inactivated the antibodies, as shown by the inability of anti-T3 $\times$ anti-DNP to inhibit lysis of M16 cells by clone 8.9 (Table 2).

Cross-linked antibodies were prepared as described in Fig. 1 legend. Two cross-linked fractions were separated from monomeric IgG by gel filtration (Fig. 1). Preliminary experiments showed that both were equally active and they were therefore used interchangeably. In the present study, hetero-cross-linked antibodies are designated 'antibody 1 $\times$ antibody 2', for example, anti-T3 $\times$ anti- K^k .

The four clones were tested for their ability to lyse M16, a human lymphoblastoid cell line bearing the HLA-DPw2 antigen, RDM4, an H-2^k mouse tumour line, and EL-4, an H-2^b mouse tumour line (Table 1). As expected, these clones lyse the M16 target but not the murine tumour cells. Moreover, lysis of M16 by clones 8.9, 8.2 and 8.5 was blocked by anti-T3 $\times$ anti- K^k , showing that anti-T3 remained active in the heteroaggregate. The main finding of Table 1 is that anti-T3 $\times$ anti- K^k causes each of the T_c -cell clones to lyse the K^k -positive RDM4 targets, but not the K^b -expressing EL-4 cells. RDM4 was also lysed if either effector or target cells were preincubated with the heteroaggregates and washed before the experiment (data not shown).

These results suggest that anti-T3 $\times$ anti- K^k cross-links K^k on RDM4 to the T3 portion of the T-cell receptor complex on the T_c -cell clones and triggers the T_c cells to lyse the RDM4 targets. Figure 2 confirms specific intercellular cross-linking, as reflected in the formation of multicellular conjugates between effectors and targets. Figure 2a, b shows that in the absence of the

Fig. 2 Conjugate formation between T_c -cell clone 8.9 and tumour lines M16 (a, c) and RDM4 (b, d) in the absence (a, b) or presence (c, d) of anti-T3 $\times$ anti-K^k. Clone 8.9 cells were labelled with fluorescein isothiocyanate as described elsewhere²³. M16 and RDM4 cells (10^7 per ml) were incubated for 10 min at 37 °C with $10 \mu\text{g ml}^{-1}$ N-hydroxysuccinimidobiotin (Sigma) in PBS, pH 8.0, washed and incubated with phycoerythrin-avidin ($20 \mu\text{l}$ of an appropriate dilution of R-phycoerythrin-avidin was added to 10^7 cells in 100 μl of PBS, pH 7.2, and incubated for 30 min at 24 °C). Conjugates were formed by mixing 8.9 cells with M16 or RDM4 cells at a 1:1 ratio, centrifuging and incubating for 20 min at 24 °C. In c and d, effectors were preincubated for 30 min at 0 °C with $10 \mu\text{g ml}^{-1}$ anti-T3 $\times$ anti-K^k before adding the target cells. After the 20-min incubation, cells were gently resuspended with a Pasteur pipette in 1 ml PBS at 0 °C and analysed with a Becton-Dickinson FACS analyser. Free 8.9 cells appear green only, free target cells appear red only and conjugates appear both red and green. 2×10^4 particles were analysed in each sample and contours were drawn through points containing 10, 20 and 40 particles. The percentages of effectors in conjugates were: a, 28%; b, 8%; c, 25%; d, 31%.

heteroaggregate, clone 8.9 forms the expected large number of conjugates with M16, but few conjugates with RDM4. By contrast, in the presence of heteroaggregates, the number of RDM4-8.9 conjugates increases dramatically while the number of M16-8.9 conjugates remains relatively unaffected. The latter observation is consistent with previous studies^{16,17} showing that anti-T3 blocks T_c -cell mediated lysis at a step following conjugate formation.

To test the specificities required for cross-linked antibodies to mediate lysis, we coupled anti-T3 to anti-dinitrophenyl(DNP), anti-T4 to anti-K^k and anti-DNP to anti-K^k, using procedures similar to those described for Fig. 1. Table 2 shows that the anti-T3 $\times$ anti-DNP confers anti-DNP specificity to T_c -cell clones; in the presence of this heteroaggregate, T_c cells lyse TNP-RDM4 and TNP-EL4, but not unmodified EL4 or RDM4. Moreover, DNP hapten in solution strongly inhibits lysis of the haptenated targets. Interestingly, T_c cells will even lyse hapten-modified chicken red blood cells (CRBC) in the presence of anti-T3 $\times$ anti-DNP. Thus, the antibody heteroaggregates seem to override the normal requirement for lysis that T_c -cell receptors bind to molecules of the major histocompatibility complex (MHC) on target cells, as it is unlikely that either CRBC or the murine T_c -cell tumour lines EL4 and RDM4 express MHC molecules, which could be recognized by the class II-specific T_c -cell clones used here.

We next investigated whether anti-T3 must be a component of the antibody heteroaggregate, or whether monoclonal antibodies against any effector cell-surface molecule would trigger lysis. For this, we tested the effect of anti-T4 $\times$ anti-K^k on lysis

Table 1 Anti-T3 $\times$ anti-K^k heteroaggregates re-target T_c cells to K^k-expressing cells

Clone	Anti-T3 $\times$ anti-K ^k	% Specific lysis of target cell		
		M16	RDM4	EL-4
8.9	—	47.0	6.6	0.8
8.9	+	11.5	53.3	0.2
8.2	—	44.9	9.1	3.3
8.2	+	20.4	43.9	—0.7
8.4	—	49.8	7.2	4.3
8.4	+	54.1	32.9	0.8
8.5	—	35.7	1.5	0.6
8.5	+	8.0	30.0	0.4

Lysis was measured in the presence or absence of $5 \mu\text{g ml}^{-1}$ anti-T3 $\times$ anti-K^k at a 10:1 effector: target ratio in a 3-h ^{51}Cr -release assay. Antibody was preincubated with effectors and targets for 30 min at 0 °C, before warming to 37 °C. Human T_c -cell clones 8.2, 8.4, 8.5 and 8.9 are specific for the HLA-DPw2 antigen^{14,18}. M16 (ref. 19) is a human Epstein-Barr virus-transformed lymphoblastoid cell line that expresses HLA-DPw1 and -DPw2 antigens. RDM4 and EL4 are H-2^k and H-2^b murine T_c -cell tumour lines. Per cent lysis was calculated as described elsewhere¹³, and spontaneous release was 8.9, 5.2 and 6.8% for M16, RDM4 and EL-4, respectively.

of M16 and RDM4. Results from experiments similar to those shown in Fig. 2 confirmed that anti-T4 $\times$ anti-K^k caused conjugates to form between clone 8.9 and RDM4 (21% of effectors were conjugated in the presence of heteroaggregate, 9% in its absence). However, this cross-linked preparation neither promoted lysis of RDM4 nor significantly blocked lysis of M16 by clone 8.9 (it has previously been demonstrated¹⁸ that anti-T4 does not inhibit lysis mediated by clone 8.9) (Table 2). In a second experiment (not shown in Table 2), T_c -cell clone 8.9 was treated with 1.5 mM trinitrobenzene sulphate and tested for lysis against RDM4 in the presence of anti-DNP $\times$ anti-K^k. Control experiments showed that anti-DNP $\times$ anti-K^k promoted specific conjugate formation between TNP-8.9 and RDM4 and that the TNP-8.9 cells were able to lyse M16. However, TNP-8.9 cells did not lyse RDM4 cells in the presence of anti-DNP $\times$ anti-K^k (<2% lysis over a concentration range of 5–40 $\mu\text{g ml}^{-1}$ heteroaggregate). Therefore, cross-linking of target cells specifically to the T4 molecule and to a presumably large number of TNP-modified components on the effector cells did not lead to lysis. These data suggest that the cross-linking of target cells directly to the T_c -cell receptor complex is a requirement for lysis. In support of this view, earlier experiments¹² showed that several hybridoma cells expressing antibodies against effector cell-surface components other than T3 are not lysed by T_c -cell clones. In addition, Kranz *et al.*¹¹ have recently shown that a mouse T_c -cell clone will lyse targets to which anti-Ti antibodies were attached, but not targets bearing antibodies that bind to other effector cell-surface components.

From current results, there seems to be a striking parallel in the way in which ADCC effector cells and T_c cells lyse target cells; in both cases, direct attachment of the target cells to the appropriate receptor (Fc γ R on ADCC¹³ effectors or T_c -cell receptor complex on T_c cells) leads to target cell lysis, and attachment to other cell-surface components on the effector cell does not. These data strongly suggest that the target-specific receptors in both systems not only mediate conjugate formation, but also have an essential role in the post-conjugate phase of the lytic process. T3 is one cell-surface component that is clearly involved in the post-conjugate phase of T_c -cell mediated lysis, because anti-T3 blocks lysis but does not inhibit conjugate formation. Nevertheless, binding of the target cell directly to T3 results in target cell death. This suggests that the local aggregation of T3 at the cell/cell interface may be instrumental in triggering lysis, and that soluble anti-T3 blocks normal T_c -cell lysis by preventing local T3 aggregation.

We have demonstrated here that the specificities of T_c cells can be altered *in vitro* simply by treating them with antibody heteroaggregates. In fact, we have now been able to direct T_c

Table 2 Specificity of T_c -cell lysis in the presence of hetero-cross-linked antibodies

Target	None	Anti-T3 $\times$ anti-K ^k	% Specific lysis of target cells by clone 8.9			
			Antibody added			
			Anti-T3 $\times$ anti-K ^k + anti-T3	Anti-T3 $\times$ anti-DNP	Anti-T3 $\times$ anti-DNP + DNP	Anti-T4 $\times$ anti-K ^k
M16	37.8	-7.0	-29.7	22.3	—	29.9
RDM4	-8.7	38.2	2.0	-8.6	—	2.1
EL-4	-4.9	-4.2	—	-4.3	—	—
CRBC	1.1	—	—	1.3	0	—
M16-TNP	55.1	—	—	32.3	43.8	—
RDM4-TNP	-8.1	—	—	40.5	7.4	—
EL-4-TNP	0.4	—	—	49.1	0.3	—
CRBC-TNP	0.8	—	—	63.9	0	—

Experiments were performed as described in Table 1 legend using clone 8.9 cells as effectors. Clone 8.5 also lysed TNP-CRBC in the presence of anti-T3 $\times$ anti-DNP in a hapten-specific manner (data not shown). In all experiments shown, $10 \mu\text{g ml}^{-1}$ cross-linked antibody was used, but 20 and $40 \mu\text{g ml}^{-1}$ of anti-T4 $\times$ anti-K^k were also tested, with results similar to those shown here. Anti-T3 ($50 \mu\text{g ml}^{-1}$, column 4) and DNP- ϵ -aminocaproate (0.1 mM , column 6) were used as inhibitors. DNP- ϵ -aminocaproate did not inhibit lysis of M16 by clone 8.9 (data not shown). Target cells were modified with TNP by incubating them for 10 min at 37°C in phosphate-buffered saline (PBS), pH 7.4, containing 3 mM trinitrobenzene sulphonate. (—) Indicates experiment not done. Negative values for per cent lysis indicate that chromium release was less than spontaneous release. In the test sample, spontaneous release values for the various targets were: M16, 28.6%; RDM4, 11.4%; EL-4, 12.4%; CRBC, 2.9%; M16-TNP, 7.4%; RDM4-TNP, 15.4%; EL-4-TNP, 4.5%; and CRBC-TNP, 3.0%.

cells to lyse every target cell for which we have had an appropriate anti-target cell antibody. Based on these observations, it is reasonable to propose that T_c cells could be directed against various pathogenic cells *in vivo*, for example against tumour cells. By using anti-T3-containing heteroaggregates, presumably all T_c cells, and not a limited number of clonotypes, would be targeted to the tumour. In addition, such heteroaggregates could also target T-helper cells to a tumour (or other lesion) where they could serve as a source of lymphokines. Finally, appropriate heteroaggregates could be used to target both T cells (using anti-T3-containing heteroaggregates) and macrophages, granulocytes and natural killer cells (using anti-Fc γ R heteroaggregates) to the same lesion. Such strategies might greatly augment the normal immune response against tumours and other pathogenic cells, and could also provide insight into the normal role of various effector cells in combating infections and neoplasms.

We thank Drs Alfred Singer, Pierre Henkart and Ralph Quinones for helpful suggestions during the preparation of the manuscript, Ms Julie Titus for help in isolating antibodies and Ms Judy Kress for typing the manuscript. P. P. is the recipient of a Fulbright fellowship awarded by the Spanish Department of Education and Culture.

Note added in proof: Staerz *et al.*²⁴ have recently shown that anti-Ti-containing heteroaggregates will re-target murine T_c cells.

Pre-B cells in κ -transgenic mice

Ursula Storb, Kathleen A. Denis*, Ralph L. Brinster† & Owen N. Witte*

Department of Microbiology and Immunology, University of Washington, Seattle, Washington 98195, USA

* Department of Microbiology and Molecular Biology Institute, University of California, Los Angeles, California 90024, USA

† Laboratory of Reproductive Physiology, School of Veterinary Medicine, University of Pennsylvania, Philadelphia, Pennsylvania 19104, USA

Recent experiments have shown that the microinjected κ -chain gene of transgenic mice is expressed in a tissue-specific fashion only in B lymphocytes^{1,2}. The next step was to determine whether, within the B-lymphocyte lineage, the κ -chain gene was expressed in a normal developmental fashion. Normally, only μ heavy(H)-chain genes, and not κ -chain genes, are expressed in pre-B cells³. To obtain cloned cell lines derived from early cells of the B-cell lineage, we transformed bone marrow cells from κ -transgenic mice with Abelson murine leukaemia virus (A-MuLV) and tested the resultant cell lines for the retention of the κ transgene and its expression in RNA and protein. We found that cells with the pre-B phenotype exist in κ -transgenic mice. We further observed that in A-MuLV-transformed cell lines from a κ -transgenic mouse with a high copy number of the transgene, the proportion of cell lines expressing κ (transgenic κ) was higher than in cell lines from normal or low copy number transgenic mice.

Bone marrow was obtained from two 4-week-old transgenic mice and one normal sibling from the same litter. The parents were a male transgenic mouse (no. 48, ref. 2) and a normal female C57BL mouse. A portion of the bone marrow cells was directly transformed by A-MuLV⁴; the rest was first cultured for 3-4 months *in vitro*⁵ and then transformed with A-MuLV.

Kidney DNA from the three donor mice was tested for the presence of the transgene by dot hybridization with a constant region (C_κ) probe and pBR322 as described previously¹. One donor had not inherited the transgene (normal littermate), whereas the two transgenic donors had different copy numbers of the transgene (see below). Apparently the father, no. 48 (ref. 2), contained mosaic germ cells, whereas only the high copy transgenes were observed in the tail DNA (R. L. O'Brien and U.S., unpublished).

All the A-MuLV-transformed cell lines from normal and transgenic mice produce μ -chain RNA (Fig. 1, Table 1). The levels of μ RNA are variable: some cells produce very low

Fig. 1 RNA analysis. *a*, Northern blot of RNA from A-MuLV-transformed cell lines obtained directly from fresh bone marrow (see text). Each lane contains 10 μ g total cellular RNA. The first 10 lanes are from cell lines of normal littermates, the next 7 are from transgenic cell lines of the high copy number mouse, the last 6 are from the low copy number mouse. Top panel shows hybridization with a M.13 DNA probe containing the V_{κ} region of MOPC-21 (the transgene)¹. Bottom panel shows the same blot, first hybridized with V_{κ} M.21 and then rehybridized with a C_{μ} -containing probe⁹. Symbols μ , κ , positions of normal μ and κ mRNAs. *b*, Dot hybridization of RNA from A-MuLV-transformed cell lines. These clones were derived by A-MuLV transformation of bone marrow cells cultured for 3–4 months *in vitro* (see text). The dots were hybridized with the probes indicated: C_{μ} , C_{κ} and V_{κ} M.21; RNAs from transgenic mice (+) and normal littermates (–). CoN, control RNA from normal spleen; CoT, control RNA from transgenic spleen. Each RNA sample was dotted in two dilutions (1 and 3 μ g for C_{μ} and C_{κ} ; 2 and 6 μ g for V_{κ}).

amounts, which may in some cases be the reason for the lack of detectable μ protein (see below). The μ RNA size appears normal, probably representing the secreted and membrane forms of the protein. The cell lines also have rearranged H-chain genes on both chromosomes, indicated by hybridization with a joining segment (J_H) probe (see Fig. 2*a, b* for the long-term bone marrow culture-derived cell lines; data not shown for the direct transformants). Thus, the presence of the κ transgene does not prevent the rearrangement or expression of endogenous μ -chain genes, nor does it seem to impose the rearrangement of particular H-chain genes; among the different A-MuLV-transformed cell lines we found several different patterns of J_H -gene rearrange-

Fig. 2 Southern blots of DNAs of A-MuLV-transformed cell lines. DNAs were digested with *Eco*RI (*a*) or *Xba*I (*b*) and Southern blots were prepared as described previously¹⁰ and probed with nick-translated DNA corresponding to the J_{H2} , J_{H3} and J_{H4} regions¹⁰. DNAs were from cell lines transformed by A-MuLV after prolonged culture of the bone marrow cells (see text). L, liver; 6.1–6.8, cell lines derived from mouse 48-6; 7.1 and 7.3, from mouse 48-7. It seems that 6.1 = 6.7 and 6.4 = 6.5 = 6.8. DNAs from direct A-MuLV transformants were digested with *Eco*RI and probed with a C_{κ} probe cloned in M13 (ref. 1). *c*, Cell lines are from normal littermates (N) and from transgenic mice 48-6 and 48-7. Arrow, tandemly repeated multiple copies of the κ transgene (14.8 kb) (~19 copies in 48-6, 5 in 48-7 cell lines) and germ line C_{κ} genes (15.2 kb).

ment. This provides further evidence that most lines are probably derived from transformation of different, independent cells, but there may be some duplication in the cell clones (Fig. 2*a, b*). Most of the cell lines produce μ protein (Fig. 3, Table 1), indicating that the μ RNA is functional. These results are analogous to previous findings with more mature B cells from transgenic mice that were immortalized by fusion with a hybridoma cell⁶, making it unlikely that the results described here are an artefact of the method of immortalization.

The differential copy number of the κ transgene was retained in the direct A-MuLV-transformed cell lines from the two mice (Fig. 2*c*). This Southern blot also shows additional bands, probably integration fragments, which differ in the cell lines from mice 48-6 and 48-7, suggesting that the transgenes are probably integrated at different sites. With respect to κ RNA, the cell lines from the two transgenic mice behaved differently; 71% of cells from the low copy number mouse 48-7, like the cells from the normal mouse, did not produce κ RNA despite the presence of κ transgenes (Table 1). The proportion of κ -producing cells from mouse 48-7 is within the range normally found in A-MuLV-transformed bone marrow cells³. Thus, even though the κ transgene is expressed in a tissue-specific manner², its presence in a B cell is not sufficient for its expression at a detectable level. True pre-B cells exist in 48-7 κ -transgenic mice. Because μ RNA is produced in these pre-B cells, transcriptional factors for H-chain genes must be present. The lack of transcription from the rearranged κ transgene suggests that different transcriptional

Table 1 Expression of κ - and μ -chain genes in A-MuLV-transformed cells from κ -transgenic mice

Cell donor	No. of cell lines*	C_{κ}	RNA V_{κ} M.21	C_{μ}	Protein†	μ	Pre-B (μ RNA only) total

* -, Without; +, with transgene.

† Not all cell lines were tested for protein. ND, not done.

factors are responsible for H-chain and κ transcription and that in pre-B cells only H-chain gene transcriptional factors exist. Alternatively, the κ transgene and normal κ -chain genes may not be in an open chromatin conformation in pre-B cells. Lastly, the differential transcription of μ - and κ -chain genes may be related to differential strength of response to the same transcriptional factors, or cofactors. It has been suggested that the tissue-specific transcriptional 'enhancer' of H-chain genes is ~20 times stronger than the analogous enhancer of κ -chain genes⁷. If the amount of transcriptional factors in pre-B cells is limiting, transcription from μ -chain genes would be favoured over κ -chain genes. The amount of μ RNA in the cell lines is at least six times lower than in spleen (Fig. 1b), which indicates a lower and perhaps limiting level of transcriptional factors.

Limiting amounts of common transcriptional factors for μ - and κ -chain genes could also explain why there was a high frequency of κ RNA-producing cells in the high copy number transgenic cell lines (Fig. 1a, Table 1). Most of the direct A-MuLV cell lines from mouse 48-6 contained detectable levels of κ RNA. The cells from mouse 48-6 have about four times as many copies of the transgene as those from mouse 48-7 (Fig. 2c). Even though the κ -transcriptional enhancer may be weaker than that of μ , its presence in ~19 copies in cells of mouse 48-6 may effectively compete with μ for occasional transcription, leading to a detectable level of κ RNA.

It seems unlikely that the difference in κ frequency of cell lines derived from mice 48-6 and 48-7 results from complete transcriptional inactivation of the transgenes in the low copy number mouse. First, we found one cell line from mouse 48-7 which transcribed the κ transgene (Table 1). Second, the levels of κ RNA encoded by the transgene in spleen cells from the two mice was the same (data not shown). Besides differential transcription, differential processing or stability of the messenger RNAs could be responsible for the relative levels of μ and κ RNAs. This would require specific processing factors and/or nucleases for μ and κ RNAs, and for the κ RNAs in the κ -positive and κ -negative A-MuLV B-cell lines. These possibilities need to be explored further, but other evidence indicates an important role for transcriptional control in the regulation of immunoglobulin mRNA levels⁸.

The distribution of κ -producing cells from mouse 48-6 between the cell lines derived by the two methods of transformation was strikingly different. No κ -producing cells were found in the transformants from prolonged bone marrow cultures (Fig. 1b, Table 1). Surprisingly, these cell lines from mouse 48-6 had lost most of the copies of the transgene and only retained a low copy number, similar to the cell lines from mouse 48-7 (not shown). This finding strengthens the argument that in the high copy cell lines the large number of κ -chain genes effectively competes for limiting transcriptional factors (see above), but alternative explanations are under investigation.

In conclusion, the data reported here support the concept of sequential activation of first H-, then κ -chain genes³. The molecular basis for this control, which aids allelic exclusion of κ genes⁶, remains to be determined. To effect allelic exclusion

Fig. 3 Analysis of immunoglobulins produced by A-MuLV transformed cell lines. *a*, Direct A-MuLV transformed; *b*, A-MuLV transformed after prolonged bone marrow culture. Cells were grown in tunicamycin and metabolically labelled with ³H-leucine¹⁰. Immunoprecipitation with polyclonal rabbit anti-mouse immunoglobulin and electrophoresis on SDS-polyacrylamide gels was carried out as described previously¹⁰. M-24 is an established A-MuLV transformed B-cell line. Normal, 48-6 and 48-7 are cell lines derived from the three respective mice. SP, normal spleen (not treated with tunicamycin); μ^* and μ , glycosylated and unglycosylated forms of μ , respectively. Oblique arrows indicate lighter forms of μ , which were consistently observed in these two cell lines; presumably they represent translates from incomplete μ RNAs (such as *D-J-C-μ*-encoded). The double bands above the κ -chains are unexplained artefacts seen in some, but not all, immunoprecipitates with the same antiserum.

of κ genes⁶, transcriptional factors for κ -chain genes seem to be required at a high level either before or at the same time as κ -chain gene rearrangement.

We thank R. L. O'Brien for restriction analysis of DNA from high and low copy number transgenic mice and Joyce St Claire for technical assistance. § To whom correspondence should be addressed.

Mobile genetic elements have been reported in prokaryotes, plants, yeast and *Drosophila* (reviewed in refs 1, 2). The only transposon-like sequences reported for mammalian organisms are closely related to retroviruses³⁻⁷, although undoubtedly other transposon families exist within the mammalian genome. Although mobile genetic elements can only be identified as such if their mobility can be demonstrated in existing populations, transposon and transposon-like elements share several common biochemical and structural features^{1,2}. Here we demonstrate that a repetitive human sequence has many of the diagnostic features of transposable elements. This 2.3-kilobase (kb) transposon-like element contains two flanking long terminal repeat (LTR)-like 350-base pair (bp) repetitive sequences, each of which begins with the sequence 5' TG... and ends with ...CA 3'. The transposon-like element is bounded by 5-bp direct repeats. Discrete-length polyadenylated transcripts from HeLa cells are homologous to the transposon-like element. Members of this transposon-like family are found in extrachromosomal circular DNA molecules.

Sun *et al.*⁸ previously described the 'O' family of repetitive sequences. A slightly different representation of two members of this family (see below) indicates that the 350-bp O family repeats begin with TG and end with CA (B. Baum, personal communication), a hallmark of the LTRs that flank transposable

elements¹⁻³. Therefore, the O repeats may be solitary LTRs, and additional O family members could be linked to longer transposon-like elements. To test this interpretation, we determined the DNA base sequence of additional members of the O family, which were isolated as described previously⁸.

One such recombinant DNA clone, λ THE 1-A, contains two members of O at opposite ends of a 1.9-kilobase (kb) *Bgl*/II restriction fragment (Fig. 1a). (This structure is called a transposon-like human element, and corresponding clones are designated THE 1; the O family is now called the 'O-LTR' family.) Subcloned restriction fragments of λ THE 1-A (Fig. 1a) were used as hybridization probes for additional λ THE clones as well as genomic DNA fragments. A 2-kb sequence flanked by two O family repeats is also observed in clones λ THE 1-B and -C (Fig. 1a). Because these three recombinant DNAs share homologous sequences and similar maps, they must be members of a repetitive sequence family. The following hybridization experiments confirm the repetitive nature of the THE 1 family.

Human DNA digested with the restriction enzymes listed in Fig. 1a was hybridized to O-LTR repeats and subcloned restriction fragments of λ THE 1-A (Fig. 1a). The *Bgl*III digest of human DNA illustrates the main results of our study (Fig. 1b). The 350-bp O-LTR repeat hybridizes to a highly repetitive 1.9-kb *Bgl*III fragment in addition to restriction fragments of other lengths (Fig. 1b), indicating that O-LTR repeats are associated with longer repetitive sequences. Subclones derived from the longer repetitive element of λ THE 1-A hybridize to many of the same genomic restriction fragments as the O-LTR family, with noticeably lower background (Fig. 1a, b). Comparison of the λ genomic clones THE 1-A, -B and -C reveals restriction site polymorphisms (Fig. 1a), many of which correspond to minor genomic restriction fragments that can be arranged as a consensus restriction map (Fig. 1a). Evidently, most of the sequences that are homologous to THE 1 family repeats share a single consensus sequence.

Dot-blot and library screening hybridizations indicate that there are ~30,000 O-LTR repeats and 10,000 copies of the internal element within human DNA (data not shown). These

Fig. 1 *a*, Genomic and clone restriction maps. Restriction fragments of THE 1-A (indicated schematically by the cross-hatched and shaded bars under the genomic consensus map) were subcloned and used as hybridization probes to the indicated restriction digests of λ THE 1-A, -B and -C and genomic DNA. Genomic digests are complicated by the appearance of a number of weak and presumably polymorphic restriction fragments (*b*). Relatively rare sites are indicated in the consensus map by dotted lines; strong sites are indicated by solid lines. The right LTR of λ THE 1-B is deleted, a finding which has been confirmed by limited base sequencing. The base sequencing strategy used for λ THE 1-A is indicated by the arrows positioned under the map of λ THE 1-A. These restriction fragments were subcloned into M13 and their sequences were determined by Messing's modifications of the Sanger dideoxynucleotide procedure and limited Gilbert-Maxam sequencing of refractory regions. *b*, Mapping of genomic restriction digests. Placental and cell culture DNAs (labelled human and HeLa respectively) digested with *Bgl*II were hybridized to the LTR family (pBRQ₄ in ref. 8) and pUC19 subclone of the 1.9-kb *Bgl*II fragment of λ THE 1-A as depicted in *a*. A highly repetitive 1.9-kb *Bgl*II fragment, as indicated by the arrow, as well as several minor bands are revealed by this hybridization. The autoradiograph was exposed overnight without an intensifying screen. The minor bands can be rationalized according to the rarer sites in the consensus map of *a*.

Fig. 4 Covalently closed circular DNAs from the Jurkat lymphoblastoid human cell line were isolated and resolved by gel electrophoresis^{12,13}. Blots of these gels were hybridized to subclones corresponding to an internal 0.38-kb *Pst*I fragment of λ THE 1-B (left panel as indicated), the 1.9-kb *Bgl*II fragment of λ THE 1-A (right panel as indicated) or the LTR-specific hybridization probe (pBR0₄ of ref. 8; data not shown). The right and left panels, which correspond to gels that were run for slightly different times, are juxtapositioned to indicate the coincidence of the bands. Circular DNA marker lengths are indicated in the left panel, which also includes a *Bgl*II digest of genomic DNA revealing the diagnostic 1.9-kb band described in Fig. 1a. As an important negative control, neither pBR nor M13 DNAs exhibited any hybridization to these gels.

that of typical retroviruses. Therefore, THE 1 family repeats should be regarded as a new class of repetitive transposon-like sequences.

Blot hybridization reveals the THE 1 structure in monkey but not in rodent DNA, so that the mobility of these sequences over long evolutionary times seems certain. However, blot hybridization of a sequence flanking THE 1-B to the DNAs of 19 individuals indicates that this particular member of the family is fixed in the human genome (data not shown). The mobility or relative immobility of this family remains to be determined.

Lymphokine dependence of *in vivo* expression of MHC class II antigens by endothelium

G. Groenewegen, W. A. Buurman & C. J. van der Linden

Department of Surgery, Biomedical Center, Hospital St Annadal, University of Limburg, Maastricht, The Netherlands

Changes in the expression of class II antigens of the major histocompatibility complex (MHC) have an integral role in the regulation of immune responses, and are brought about *in vitro* by soluble mediators¹⁻⁴. However, the mechanism that underlies *in vivo* expression of MHC class II antigens in, for example, endothelial cells in the absence of immunological stimulation has not been studied. We demonstrate here that expression of MHC class II antigens is not a constitutive property of endothelial cells, for MHC class II antigen-positive endothelial cells do not express these antigens during treatment with the immunosuppressive agent cyclosporin A. *In vivo* MHC class II antigen expression by canine endothelial cells is therefore dependent on factors, probably the lymphokine γ -interferon produced by the immune system, whose secretion is inhibited by cyclosporin A.

γ -Interferon (IFN- γ) has been identified as the lymphokine responsible for the augmented MHC class II antigen expression observed on monocytes *in vitro*⁴, although recently an intermediate messenger, produced by murine tumour macrophages in response to IFN- γ , has been reported to be involved in this process⁵. The MHC class II antigen-inducing capacity of IFN- γ has also been clearly demonstrated *in vitro* for endothelial cells from human umbilical vein⁶ and fibroblasts⁷. Furthermore, there is evidence that the expression of these antigens changes on immunological stimulation⁸⁻¹². For example, rat skin^{9,10} and gut epithelium¹⁰, both normally MHC class II antigen-negative cells, express these antigens during graft-versus-host disease and local infections¹¹. We therefore investigated whether the normal 'physiological' expression of MHC class II antigens is dependent on factors such as IFN- γ .

An *in vivo* model was selected that assessed the effect of lymphokines on normal endothelial cell MHC class II antigen expression by analysing the response to cyclosporin A; this compound has been shown to inhibit the *in vitro* production of the factor responsible for MHC class II antigen expression¹³⁻¹⁵. The canine model was chosen because the dog resembles humans¹⁶⁻¹⁹ in exhibiting MHC class II antigens on the capillary endothelial cells of the skin and the glomerular and peritubular capillary endothelium of the kidney.

MHC class II antigen expression was studied in skin and kidney biopsies from five dogs treated with cyclosporin A. The drug was given once daily as an oral solution (Sandoz), and drug blood levels were monitored by HPLC and maintained between 0.2 and 0.4 mg ml⁻¹. The cyclosporin A doses administered ranged from 15.0 to 22.5 mg per kg per day. Drug treatment did not affect the health of the dogs. Renal function, as assessed by serum creatinine and urea concentrations, was unaffected; creatinine concentrations were 40-60 μ mol l⁻¹ during treatment (normal range in dogs 30-120 μ mol l⁻¹). Wound healing of the biopsy incisions was also unimpaired.

The expression of MHC class II antigens during cyclosporin A treatment was studied in tissue biopsies by indirect immunofluorescence using two monoclonal anti-MHC class II antibodies (Fig. 1). Renal biopsies taken from the first dog studied on days 10, 19 and 32 of treatment revealed that MHC class II antigens were present before treatment (Fig. 1a), but could not be detected during treatment (Fig. 1b); the antigens were consistently absent from the renal vasculature in all biopsies taken after 10 days of cyclosporin A treatment.

Endothelial cells were identified using the marker protein, FVIII-related antigen²⁰ (Fig. 2). In renal biopsies from untreated dogs, both antibodies stained endothelium of glomerular capil-

Fig. 1 Distribution of MHC class II antigens in the kidney before (a) and during (b) treatment with cyclosporin A ($\times 400$). Monoclonal antibodies 7.2 (ref. 25) and 7.5.10.1 (ref. 26), known to cross-react with canine MHC class II antigens²⁷, were used in the ascites form. Both monoclonal antibodies gave identical patterns of immunofluorescence. The reactivity of antibody 7.5.10.1 is shown. a, A biopsy taken before treatment, showing part of a glomerulus (left margin) and several unstained tubules; the glomerular endothelium stained for MHC class II antigens, as did peritubular capillary endothelium. Biopsy b, taken after 10 days of cyclosporin A administration, is devoid of antigens reacting with anti-MHC class II reagents, even at antibody concentrations 10-fold higher than the concentration that appeared on titration to be optimal in biopsies of untreated dogs.

Methods. Healthy beagles from the colony of the University of Maastricht were regularly screened for infections; the last vaccination had been given at least 12 months before the experiment. Tissue specimens, obtained by open biopsies, were snap-frozen in isopentane, cooled on dry ice. Tissue sections ($4\ \mu\text{m}$) were fixed in acetone at -20°C and rehydrated in phosphate-buffered saline (PBS) at room temperature. Subsequently, sections were incubated for 30 min at room temperature with the desired antibody, washed for 15 min in PBS and incubated with an appropriate fluorescein-labelled second antibody. Antibodies were used at twice the concentration shown by titration to be still saturating, to achieve maximal sensitivity of the fluorescence technique. After a final wash the section was embedded in glycerol.

laries and vasculature around the tubules, whereas tubular cells and basement membrane structures were not stained. Before and during treatment with cyclosporin A, the distribution of FVIII-related antigen in endothelium was unchanged. However, MHC class II antigen distribution differed before and during treatment. Our findings were confirmed in a second dog treated with cyclosporin A and biopsied on days 10, 20 and 33 of treatment. In three other dogs, MHC class II antigens could not be detected in renal biopsies taken on day 20 of treatment, whereas the distribution of FVIII-related antigen remained unchanged.

Table 1 summarizes the results of skin and kidney biopsies. The expression of FVIII-related antigen was similar before and during treatment. However, endothelial expression of MHC class II antigens was absent in biopsies taken on day 10 of treatment, whereas before treatment the antigens were clearly present on endothelial cells. Continued treatment until day 25 resulted in a continued absence of the antigens on endothelial cells, whereas the distribution of FVIII-related antigen was unaffected. The fact that the distribution of this marker antigen was unchanged with treatment makes it unlikely that the disappearance of MHC class II antigens from the vasculature of both skin and kidney was caused by a toxic effect of cyclosporin A on endothelium.

In contrast to the disappearance of the endothelial MHC class II antigens, the expression of these antigens by a second vascular bed, the Langerhans cells of the skin, was unaffected by cyclo-

Fig. 2 Distribution of FVIII-related antigen in the kidney before (a) and during (b) treatment with cyclosporin A ($\times 400$). Antiserum specific for dog FVIII-related antigen²⁸ was used to identify endothelium in tissue sections. In biopsies a and b, taken, respectively, before and after 10 days' cyclosporin A administration, endothelial cells of glomerular and peritubular capillaries are stained. In a, a glomerulus is partially visible in the upper left-hand corner; b, glomeruli are visible in the upper right-hand corner and on the left margin of the photomicrograph.

sporin A treatment (Table 1). Whereas treatment for 10 days resulted in the loss of antigens from endothelium, treatment for as long as 25 days caused no change in MHC class II antigen expression on skin Langerhans cells.

In vitro MHC class II antigen expression on endothelial cells is induced and maintained by lymphokines. Cyclosporin A does not influence lymphokine-induced MHC class II antigen expression on endothelial cells *in vitro*, but has an effect via inhibition of the production of lymphokines responsible for antigen expression^{13,14}. Similarly, the expression of MHC class II antigens on endothelium *in vivo* seems to be lymphokine-dependent, as treatment with cyclosporin A, which inhibits the production of the relevant factors, results in the observed decreased expression of MHC class II antigens on endothelium in skin and kidney. Previous studies have already suggested that the immune system affects the expression of these antigens⁸⁻¹². The present study now shows that the immune system sustains the normal expression of MHC class II antigens on endothelium by means of lymphokines.

Although the nature of the lymphokine(s) involved *in vivo* is unknown, it seems likely to be IFN- γ , because this lymphokine is known to induce the expression *in vitro* of MHC class II antigens^{4,6,7} and its production is inhibited by cyclosporin A¹⁵. Our data strongly suggest that basal secretion of IFN- γ ²¹ is the cause of the 'normal' MHC class II antigen expression on endothelial cells. The expression of MHC class II antigens *in vivo* on capillary and venous endothelium and not on arterial endothelium suggests a difference in the sensitivity of these cells to IFN- γ , since, *in vitro*, antigen expression by arterial endothelium can be induced by lymphokines^{13,14}. During immunological stimulation, high concentrations of IFN- γ can induce the expression of MHC class II antigens on cells with low sensitivity to this lymphokine. Differences in reactivity to lymphokines might be part of the mechanism regulating the expression of MHC class II antigens on different cell types and therefore immunological responsiveness.

Our experiments demonstrate that regulation of MHC class II antigen expression on endothelial cells and on Langerhans cells of the skin is different, the former being abrogated by cyclosporin A, with the latter being unaffected. The consequence of this difference in the allograft situation will depend on the species. In the rat model it can be assumed that the donor passenger cells will be replaced by recipient cells. Because only

Table 1 Expression of MHC class II antigens in skin and kidney biopsies from dogs, before and during treatment with cyclosporin A

	Kidney		Skin

During treatment	-	-	-	+

MHC class II antigen expression was studied with monoclonal antibodies using an indirect immunofluorescence technique. The presence or absence of antigens is indicated, respectively, by + and -.

passenger cells express MHC class II antigens in the rat kidney, the disappearance of these cells results in complete loss of donor-type MHC class II antigens, leading to long graft survival²². In man and dog, however, the expression of MHC class II antigens by endothelial cells prevents the disappearance of donor-type MHC class II antigens from an allograft. The present data show that removal can be achieved by cyclosporin A, thus suggesting an important new mode of action for this reagent in prolonging allograft survival.

We believe this to be the first demonstration that the expression of MHC class II antigens *in vivo* on endothelial cells is not a constitutive property of these cells. The expression *in vivo* on capillary endothelium in the canine kidney and skin is sustained by the immune system via lymphokines. The presence of MHC class II antigens on the capillary endothelial cells may be a consequence of the rheological characteristics of the vessels lined by these cells. The conditions for interaction between lymphocytes and endothelial cells, which are known to function as antigen-presenting cells^{23,24}, are most favourable on these MHC class II-positive capillary endothelial cells.

The variations in the expression of MHC class II antigens by endothelial cells as a result of products of the immune system, suggest new insights into the control of immune responses, and offer interesting opportunities for evaluating immune status in patients. Moreover, the abrogation of endothelial MHC class II antigen expression caused by cyclosporin A offers a new explanation for its immunosuppressive effect.

We thank Mrs G. M. A. A. Jeunhomme, Mrs A. J. J. M. Daemen and Mrs E. E. M. Spronck for technical assistance and Mrs K. Spronck for secretarial assistance. Cyclosporin A was a gift of Mr Stokvis (Sandoz). Cyclosporin A concentrations were determined by the Pharmacological and Toxicological Laboratory, Hospital St Annadal, Maastricht, The Netherlands. Antiserum against canine FVIII-related antigen was a gift of Professor Dr Bouma. This work was supported by grant C81.297 from Nier Stichting Nederland and grant 29.57.10 from Fungo.

Subtle structural alterations in the chains of type I procollagen produce osteogenesis imperfecta type II

Jeffrey Bonadio & Peter H. Byers

Departments of Pathology and Medicine and the Center for Inherited Disease, University of Washington, Seattle, Washington 98195, USA

Although the perinatal lethal form¹ of osteogenesis imperfecta (OI type II) occasionally results from large rearrangements within the genes encoding type I collagen²⁻⁵, most mutations are far more subtle. The complexity of the human collagen genes⁶ precludes cloning and sequencing each gene from every patient, and we have therefore developed an approach to localizing mutations at the protein level. We report here that cells cultured from 15 infants with OI type II synthesized both normal type I procollagen and a form that was unstable, poorly secreted and excessively modified. Abnormal procollagen from different strains was overmodified to different extents. The patterns of overmodification we observed are best explained by mutations that disrupt the Gly-X-Y sequence of pro α chains, and thus alter the rate of propagation of triple helix from COOH-terminus to NH₂-terminus⁷. As a consequence, a given mutation allows overmodification of all three chains in a molecule NH₂-terminal to its position in the triple helix.

After pulse labelling with ³H-proline for 16 h, each of the 15 OI cell strains secreted pro α 1(I) and pro α 2(I) collagen chains with normal mobility and others with delayed mobility (Fig. 1a). The OI cells retained more pro α (I) and pro α 2(I) chains than control cells, and most of the intracellular procollagen consisted of chains with delayed mobility.

After treatment with pepsin, which removes the NH₂- and COOH-terminal propeptide extensions from type I procollagen molecules in triple helical conformation⁸, the OI α 1(I) and α 2(I) chains migrated as doublets (Fig. 1b). One chain from each doublet co-migrated with α 1(I) and α 2(I) chains from control cells and the other chain migrated more slowly than normal.

In the presence of α , α' -dipyridyl, which inhibits most of the intracellular modification of type I procollagen⁹, the OI cells synthesized only pro α 1(I) and pro α 2(I) chains, which co-migrated with control chains (Fig. 1c). Thus, the slow mobility of the abnormal pro α (I) and pro α 2(I) chains was apparently due to excessive modification, and the mutation in each OI cell strain described here was not a large insertion (or deletion^{10-14,29}) but was either a single amino-acid substitution or an insertion or deletion that we could not detect by SDS-polyacrylamide vertical slab gel electrophoresis (PAGE)¹⁵.

To determine the distribution of overmodification along the triple helix, we cleaved collagen-sized molecules asymmetrically with fibroblast collagenase (Fig. 1d). For some cell strains (for convenience these strains are designated group C), the abnormal α 1(I) and α 2(I) chains yielded a COOH-terminal B fragment and NH₂-terminal A fragment¹⁶, which were both overmodified. For other cell strains, only the NH₂-terminal A fragment was overmodified (groups B and A).

We further defined the extent of increased modification by the relative migration of each of four detectable CNBr peptides from abnormal α 1(I) chains (Fig. 1). For group C cell strains the entire triple helix was overmodified, for group B cell strains overmodification began near the fibroblast collagenase cleavage site, and for group A cell strains overmodification began

Fig. 1 a, Electrophoretic separation of pro α chains synthesized by OI and control cells. Three patient groups were identified based on the distribution of excessive post-translational modification within the triple helical domain (see Figs 2, 4). These groups designate biochemically distinguishable cell strains and do not correspond to the recently proposed clinical sub-classification of OI type II²⁵. Indeed, all patients described here fit the OI type IIA classification. There were seven cell strains in group A, three in group B and five in group C. The data from one representative of each group are shown. Two points emerge from these data. First, the electrophoretic mobilities of the pro α 1(I) and pro α 2(I) chains of some molecules are not normal. Second, there is considerable intracellular retention of abnormal pro α 1(I) and pro α 2(I) chains. The identity of bands with normal and delayed mobility was determined by CNBr peptide mapping (data not shown). **b**, Electrophoretic separation of α chains. The pro α chains synthesized by the OI type II cells were converted into two forms of α 1(I) and α 2(I), with one form of each chain migrating more slowly than normal and the other form co-migrating with the control (arrows indicate medium and cell-layer α 1(I) chains with delayed mobility). The delayed mobility of the abnormal α 1(I) and α 2(I) chains differed among the three groups; the delay was greatest for the abnormal α chains synthesized by cells from group C, intermediate for α chains from group B and least for α chains from group A. Resistance to peptic attack indicated that the abnormal pro α chains were incorporated into molecules that were triple helical in the conditions of digestion.

c, Electrophoretic separation of unmodified pro α chains. Only pro α 1(I) and pro α 2(I) chains that co-migrated with control chains were synthesized by the OI cell strains. The extent of hydroxylation of prolyl and lysyl residues and glycosylation of hydroxylysyl residues of type I procollagen synthesized by OI type II cells in culture has been measured directly by Steinmann *et al.*¹⁸ and by Bateman *et al.*²¹. Both studies found that prolyl hydroxylation was slightly increased over control levels and that lysyl hydroxylation and hydroxylysyl glycosylation were markedly increased, the overmodified pro α chains migrated more slowly on SDS-PAGE than their normal counterparts, and the difference in mobilities was abolished if the OI cells were pulse-labelled in the presence of α, α' -dipyridyl. **d**, Electrophoretic separation of α -chain fragments after cleavage with fibroblast collagenase. Type I collagen molecules synthesized by cell strains from group C yield A- and B-chain fragments that migrate as doublets (arrow indicates overmodified α 2(I)^B fragment). By contrast, only the A fragments from collagen synthesized by cell strains from groups B and A migrate as doublets while the B fragments co-migrate with the control.

Methods. **a**, Dermal fibroblast cell strains were established from explants of skin as described previously^{10,15}. Cells were plated at a density of 2.5×10^5 in 35-mm culture dishes and allowed to attach and spread overnight. The cells were preincubated for 2–4 h in 0.7 ml of serum-free Dulbecco's modified Eagle's medium (DMEM) containing $50 \mu\text{g ml}^{-1}$ of ascorbic acid. The medium with ascorbic acid was replaced with fresh medium and ascorbate and $[2,3,4,5\text{-}^3\text{H}]$ proline (101 Ci mmol^{-1} ; Amersham) was added for 17 h. The medium and cell layer were then collected separately into protease inhibitors¹⁵, dialysed into 1 mM ammonium bicarbonate containing the same inhibitors, and lyophilized. The dried samples were dissolved in electrophoresis sample buffer, and the proteins were denatured by boiling for 5 min. The proteins were separated in reducing conditions by SDS-PAGE with 2 M urea added to the buffers to enhance separation of pro α chains²⁶. Gels were processed for fluorography with ENHANCE (NEN). **b**, Medium and cell-layer proteins were collected as described above, dialysed into 0.5 M acetic acid, pH 2.4, and digested with pepsin ($50 \mu\text{g ml}^{-1}$; Worthington) for 12–16 h at 4°C. The reaction was stopped with pepstatin ($0.5 \mu\text{g ml}^{-1}$; Sigma). The samples were lyophilized and prepared for electrophoresis in denaturing but non-reducing conditions. **c**, Cells in culture were plated as before and then preincubated for 2 h in 0.7 ml of serum-free DMEM and 0.5 mM α, α' -dipyridyl (Sigma). The cells were then pulse-labelled with ^3H -proline in fresh medium plus α, α' -dipyridyl for 4 h. The cell-layer proteins were collected as described above and the constituent proteins were separated by SDS-PAGE in reducing conditions. Pro α chains from the medium of control cells labelled for 4 h in the absence of α, α' -dipyridyl have been separated in an adjoining lane for comparison. **d**, Collagen-sized molecules from the medium (after pepsin digestion) were dialysed into 50 mM Tris-HCl buffer pH 7.5, containing 10 mM CaCl_2 , then digested for 24 h at room temperature with fibroblast collagenase (final concentration $\sim 1.0 \mu\text{g}$ collagenase per $10 \mu\text{g}$ collagen). Differences in the relative migration of A- and B-chain fragments produced by the control and OI cell strains result from slight differences in the composition of SDS-PAGE.

NH_2 -terminal to this cleavage site within the domain of the triple helix defined by the α 1(I)CB7 peptide.

The increase in post-translational modification was accompanied by a decrease in thermal stability of the abnormal collagen molecules (Fig. 3). Molecules secreted by cells from group C had melting temperatures in the range 36–38°C, those secreted by cells from group B melted in the 38–39°C range, and those secreted by cells from group A melted in the 39–41°C range. The melting temperature of normal collagens secreted by OI cell strains and collagens secreted by control cell strains was 41.5–42.5°C. Thus, the abnormal OI molecules with the lowest melting temperatures were overmodified to the greatest extent.

These OI type II cell strains in culture synthesize unstable procollagen molecules that are excessively modified and poorly secreted. Because only some of the type I procollagen molecules from each strain are affected and because overmodification is

often asymmetrically distributed within the triple helical domain, we consider that the mutations harboured by these strains are in the genes encoding the pro α chains themselves. Their principal effect is to destabilize the triple helix of molecules incorporating a mutant chain.

Formation of a collagen triple helix requires a glycine in every third position¹⁷, and the structure is stabilized by hydrogen bonds that depend on hydroxyprolyl residues in the Y-position of repeating Gly-X-Y triplets. Hydroxylation of prolyl and lysyl residues begins on nascent chains and ceases when a stable triple helical conformation is achieved. Mutations which result in substitution for a glycine or in small deletions or insertions that disrupt the Gly-X-Y sequence could each produce an unstable triple helical domain and, as a consequence, cause the intracellular retention and excessive modification of affected molecules. As overmodification is often asymmetrically dis-

Fig. 2 CNBr peptides of $\alpha 1(I)$ and $\alpha 2(I)$ chains. We describe the migration of CNBr peptides derived only from $\alpha 1(I)$ chains because this chain yields four peptides from the region of the type I procollagen molecule that we are studying, whereas $\alpha 2(I)$ chains yield only two large peptides. The overmodified $\alpha 1(I)$ chain from group C OI cell strains yielded an array of CNBr peptides similar to the control, except that each peptide was delayed in mobility. The overmodified $\alpha 1(I)$ chain from group B cell strains yielded $\alpha 1(I)CB7$, $\alpha 1(I)CB8$ and $\alpha 1(I)CB3$ peptides with delayed mobility and an $\alpha 1(I)CB6$ peptide which co-migrated with $\alpha 1(I)CB6$ from the normal $\alpha 1(I)$ chain synthesized by the OI cells and from the control $\alpha 1(I)$ chain. The overmodified $\alpha 1(I)$ chain from group A cell strains yielded a single peptide in the region of $\alpha 1(I)CB7$ and $\alpha 1(I)CB8$ that migrated slightly more slowly than the normal $\alpha 1(I)CB7$ peptide, a peptide which migrated more slowly than $\alpha 1(I)CB3$, and a peptide that co-migrated with $\alpha 1(I)CB6$. We have shown by CNBr peptide mapping of these α chains after cleavage with fibroblast collagenase (see also ref. 15) that the large peptide spot migrating slightly more slowly than the normal $\alpha 1(I)CB7$ peptide consisted of overmodified $\alpha 1(I)CB7$ and $\alpha 1(I)CB8$ peptides (data not shown). Taken together with the results of fibroblast collagenase cleavage, we concluded that the abnormal type I procollagen molecules synthesized by the various OI cell strains were not overmodified to the same extent; for group C the entire triple helix was overmodified, for group B overmodification began near the fibroblast collagenase cleavage site, and for group A overmodification began NH_2 -terminal to this site within the domain of the triple helix defined by the $\alpha 1(I)CB7$ peptide. The line diagrams of the $\alpha 1(I)$ chains indicate the COOH-terminal end of the domain of increased post-translational modification (arrows). The vertical relationship between closed (OI) and open (normal) circles indicates the relative migration of CNBr peptides during electrophoresis.

Methods. Proteins were separated in the first dimension on 5% SDS-PAGE in denaturing but nonreducing conditions. The lanes were cut out and the proteins were digested in the gel with CNBr (100 mg ml⁻¹ in 70% formic acid; Sigma) for 2 h at room temperature^{10,15,27}. Each gel strip was washed with water for three 20-min periods, equilibrated for 20 min with sample buffer lacking SDS and urea, then placed horizontally over a 12.5% gel (second dimension) that contained no urea. The strips were overlaid with sample buffer containing dithiothreitol and 5% SDS, and the CNBr peptides were separated by electrophoresis.

tributed, we think that triple helix formation, which normally begins at the COOH-terminus of the helix and propagates toward the NH_2 -terminus⁷, proceeds at an appropriate rate until the region of the mutation is reached. Thereafter, the rate of formation of a stable triple helix is delayed and (because both pro $\alpha 1(I)$ and pro $\alpha 2(I)$ chains are excessively modified) all chains in abnormal molecules are available to the post-translational modifying enzymes for longer than normal^{15,18-21}. Assuming heterozygosity^{15,18} and the random assortment of nascent pro α chains in the rough endoplasmic reticulum as pro $\alpha 1(I)$ and pro $\alpha 2(I)$ chains associated to form trimers, only a portion of the procollagen molecules synthesized would be expected to contain a mutant chain.

These concepts are supported by studies which showed that a cysteine substitution within the triple helix of $\alpha 1(I)$ chains resulted in the overmodification, intracellular retention and instability of all molecules that contained the mutant chain¹⁸. Sequence analysis (D. Cohn, B. Steinmann, R. E. Gelinas and P. H. Byers, manuscript in preparation) has identified a single base substitution in a glycine codon that results in a Gly $\rightarrow$ Cys substitution 27 amino acids from the COOH-terminus of $\alpha 1(I)$ chains encoded by this allele. As the entire length of the triple helix of abnormal molecules was shown to be overmodified, the

Fig. 3 The thermal denaturation temperature (T_m) of collagens secreted by representatives of OI type II cells in groups A, B and C.

Methods. Pepsin-digested procollagens from the medium were dissolved in 700 μ l of 0.4 M NaCl, 0.01 M Tris-HCl, pH 7.4. The samples were placed in a water bath at 30 °C and then warmed to 43 °C at a rate of 5 °C h⁻¹. Aliquots (36 μ l) were removed at 0.5 °C increments, rapidly cooled to 20 °C and then digested with trypsin (100 μ g ml⁻¹ final concentration; Worthington) for 2 min at 22 °C²⁸. The reaction was stopped by adding phenylmethanesulphonyl fluoride and SDS to achieve a final concentration of 2 mM and 2%, respectively. The whole mixture was placed in boiling water for 3 min. The proteins were separated by electrophoresis on 5% SDS-polyacrylamide gels containing 0.5 M urea. Fluorograms were quantitated by scanning gel densitometry. The slanted arrows below the top three fluorograms indicate the T_m of normal collagen molecules; the vertical arrows indicate the T_m of each abnormal molecule. In a separate experiment (data not shown) we have shown that the T_m of normal collagen secreted by the representative cell strain from group C was 41.5 °C.

Fig. 4 Nature and location of mutations in the α chains of type I collagen synthesized by the cells from 17 patients with type II osteogenesis imperfecta. Circles indicate the sites at which increased post-translational modification begins in type I collagen molecules from 15 OI type II cell strains for which the mutation does not change the apparent length of pro α chains. Although arrayed along the $\alpha 1(I)$ chain, our data do not distinguish between mutations in $\alpha 1(I)$ or $\alpha 2(I)$ chains. The arrow indicates the fibroblast collagenase cleavage site. Bars indicate the approximate size and location of the deletion from $\alpha 1(I)$ and $\alpha 2(I)$, respectively, in two OI type II cell strains discussed previously^{10,11,22}.

position of the mutation in this cell strain is correlated precisely with the extent of overmodification. It is also notable that the abnormal type I procollagen molecules synthesized by OI cell strains harbouring large deletions are also overmodified, and the extent of overmodification can be correlated with the position of the mutation in the molecule.

Mutations that do not change the apparent length of the pro α chains of type I procollagen account for most of the mutations which give rise to the OI type II phenotype (Fig. 4). To date, cell strains from only three infants with OI type II have been shown to synthesize procollagen molecules that harbour deletions from either pro $\alpha 1(I)$ or pro $\alpha 2(I)$ ^{10-14,22,29}. In contrast, the 15 cell strains described here, 8 others described in detail elsewhere^{15,18,21} and 43 others that we have partially characterized (unpublished) synthesized molecules in which the mutation does

not result in a detectable change in pro α chain length. While the nature and location of these mutations will have to be determined by gene or messenger RNA sequence studies, mapping the sites of structural alterations in mutant proteins augments S₁ nuclease mapping strategies^{23,24} and identifies a small region within a large collagen gene for detailed study.

We thank the many physicians and families who provided us with skin biopsies from infants with OI type II, Dr Eugene Bauer for providing the fibroblast collagenase, and Nancy Higgins and William Dickie for preparing the manuscript. This work was supported in part by grants from the NIH (AM-21557, AM-07171, and GM-15253) and by a Clinical Research Grant (6-298) from the March of Dimes Birth Defects Foundation. J.B. is the recipient of an NIH individual fellowship award (AM-07171); P.H.B. was an Established Investigator of the American Heart Association during the tenure of this study.

Sliding distance of actin filament induced by a myosin crossbridge during one ATP hydrolysis cycle

Toshio Yanagida, Toshiaki Arata & Fumio Oosawa

Department of Biophysical Engineering and Science, Osaka University, Toyonaka, Osaka, Japan

Muscle contraction results from a sliding movement of actin filaments induced by myosin crossbridges on hydrolysis of ATP^{1,2}, and many non-muscle cells are thought to move using a similar mechanism³⁻⁵. The molecular mechanism of muscle contraction, however, is not completely understood^{6,7}. One of the major problems is the mechanochemical coupling at high velocity under near-zero load⁸⁻¹³. Here, we report measurements of the sliding distance of an actin filament induced by a myosin crossbridge during one ATP hydrolysis cycle in an unloaded condition. We used single sarcomeres from which the Z-lines, structures which anchor the thin filaments in the sarcomere, had been completely removed by calcium-activated neutral protease (CANP)¹⁴ and trypsin, and measured both the sliding velocity of single actin filaments along myosin filaments and the ATPase activity during sliding. Our results show that the average sliding distance of the actin filament is ≥ 600 Å during one ATP cycle, much longer than the length of power stroke of myosin crossbridges deduced from mechanical studies of muscle, which is of the order of 80 Å (for example, ref. 15).

Myofibrils were prepared from glycerinated crab (*Portunus trituberculatus*) leg muscle. Because the crab muscle has a long sarcomere (~ 7 μ m; thin and thick filaments are 2.7 and 4.8 μ m long, respectively), the sarcomere shortening takes a long time and the shortening velocity can be measured using an optical microscope. Figure 1a, b shows phase contrast and fluorescence images, respectively, of a myofibril labelled with phalloidin tetramethylrhodamine (PDTMR). In Fig. 1b, thin filaments only are bright because PDTMR specifically binds F-actin¹⁶. Figure 1c is a fluorescence micrograph of single sarcomeres in myofibrils from which the Z-lines have been removed. When 5 mM ATP was added to the single sarcomeres in the absence of Ca²⁺ at 0°C, thin filaments were dissociated from the thick filaments and dispersed into the solution. Single F-actin filaments labelled with PDTMR can be clearly observed in solution using the fluorescence microscope¹⁷. We confirmed that the thin filaments were completely dissociated from the A-band and the dispersed filaments single, not bundled (Fig. 1d). This point was also confirmed by electron microscopy. The treatment with CANP

and trypsin thus completely digested the Z-lines, leaving no structures to interconnect the thin filaments.

Using single sarcomeres without Z-lines, we next measured the sliding velocity of single thin filaments along thick filaments and the ATPase activity during sliding. Figure 2 shows sequential fluorescence micrographs of a single sarcomere without Z-lines during shortening at 5°C. The shortening velocity of PDTMR-labelled single sarcomeres was measured directly. Shortening was initiated by rapidly adding a small drop of ATP solution (final concentration 5 mM) to single sarcomeres which had sedimented and weakly adhered to the surface of a glass cell in rigor solution containing an ATP regenerating system and 0.2 mM CaCl₂ (Fig. 2). Thin filaments immediately started to slide into the H-band and met those from the opposite side at the centre of the H-band (M-line) 0.20-0.25 s after ATP addition. The velocity decreased but the shortening continued until the filaments had overlapped. The sliding velocity (V_s) of thin filaments along thick filaments in the H-band was 4.7 ± 0.5 μ m s⁻¹ at 5°C. The shortening velocity of single sarcomeres was also measured by monitoring the increase in light-scattering intensity of the sarcomere suspension after rapidly mixing it with ATP using a stopped-flow apparatus (Fig. 3). The shortening velocity obtained from the initial rise in the light-scattering intensity (5.3 ± 0.5 μ m per half-sarcomere per s at 5°C) agreed well with that measured directly under a fluorescence microscope (Table 1). The shortening velocity of the sarcomeres was about 1.7 times higher than the maximum shortening velocity of a muscle fibre under the same conditions (3.0 ± 0.2 μ m per half-sarcomere per s at 5°C). This does not result from the removal of the Z-lines because the shortening velocity of myofibrils before the removal was 1.5-2 times faster than this. Arata *et al.* have reported that the shortening velocity of rabbit psoas myofibrils (>10 μ m per half-sarcomere per s at 0°C) is also much higher than the maximum velocity of muscle fibres (<2 μ m per half-sarcomere per s)¹⁸. These high values do not result from the fact that shortening was initiated by adding ATP to actomyosin rigor complexes in myofibrils, because the shortening velocity was the same when initiated by adding Ca²⁺ to relaxed myofibrils. Therefore, these high velocities probably result from the removal of some connective materials^{19,20} during preparation of the myofibrils. Such a high velocity is also seen in proteoplasmic streaming in *Nitella* cells³ and movement of small organelles along actin cables in *Chara* cells²¹ (60-80 μ m s⁻¹ at room temperature) which are believed to be driven by the actin-myosin sliding movement.

Figure 3 shows the time course of ADP liberation from single sarcomeres without Z-lines after they had been rapidly mixed with ATP at 5°C under the same conditions as those used for

Fig. 1 *a, b*, Phase contrast and fluorescence images, respectively, of a crab myofibril labelled with PDTMR. A diagram of the sarcomere is also shown. A, A-band; H, H-band; Z, Z-line; a, thin filament; m, thick filament; M, M-line. *c*, Fluorescence images of single sarcomeres labelled with PDTMR after removal of Z-lines from myofibrils by CANP and trypsin. Note that the length of thin filaments in the single sarcomere is 2–2.5 μm , 0.2–0.5 μm shorter than the original length of 2.7 μm because part of the thin filaments at the free end (Z-line side) was mechanically broken during the preparation. Therefore, the Z-lines of the sarcomeres used were not only chemically but also mechanically removed. *d*, Fluorescence images of single thin filaments dissociated from sarcomeres in a relaxing solution (rigor (100 mM KCl, 7 mM MgCl_2 , 20 mM Tris-HCl pH 7.5) + ATP + EGTA). Note that all fluorescent filaments have the same brightness which is uniform along the filament. The filaments could not be distinguished from the fluorescence images of single thin filaments purified from rabbit skeletal muscle. Scale bars, 5 μm .

Methods. Myofibrils were prepared from glycerinated crab muscle and homogenized for 5 min in rigor solution with a Waring blender. CANP was obtained from the crab muscle and purified by the method of Ishiura *et al.*³². CANP specifically digests the Z-lines and hardly affects other protein^{14,33}. Thin filaments (F-actin) in myofibrils or sarcomeres were specifically labelled with PDTMR by immersing them in rigor solution containing $\sim 1 \mu\text{M}$ PDTMR for a few minutes at 0 °C. Treatment with PDTMR do not affect ATPase activity in the presence of Ca^{2+} (ref. 34). Fluorescent myofibrils and sarcomeres were observed with an inverted microscope (Zeiss IM 35) equipped with epifluorescence optics, a Zeiss Neofluor $\times 100$ objective (oil immersion, NA, 1.3), a 100 W mercury arc lamp and a Zeiss rhodamine filter ($\lambda_{\text{excitation}} = 540 \text{ nm}$; $\lambda_{\text{emission}} = 580 \text{ nm}$). Fluorescent single thin filaments were observed with a laser fluorescence microscope system described elsewhere³⁵. The fluorescent images were recorded on videotape with a high-sensitivity television camera (Ikegami SIT camera CTC-900; time resolution 17 ms) and a video recorder (Victor CR 6650L).

Table 1 Sliding distance of thin filament induced by a myosin crossbridge during one ATP cycle

Temperature (°C)	Sliding velocity of thin filament, V_s ($\mu\text{m s}^{-1}$)		ATPase activity, V_{ATP} (ADP mol per myosin mol s^{-1})*	Sliding distance of thin filament per ATP cycle, M (Å)†	
	Light scattering	Fluorescence microscope		Light scattering	Fluorescence microscope
5	5.3 $\pm$ 0.7(5)	4.7 $\pm$ 0.8(20)	1.0 $\pm$ 0.3(4)	680 $\pm$ 240	600 $\pm$ 230
10	12 $\pm$ 1.5(5)	—	—	—	—
15	20 $\pm$ 2.0(5)	—	4.1 $\pm$ 0.5(3)	650 $\pm$ 170	—

All observed values (V_s and V_{ATP}) are shown as mean $\pm$ half-range. Numbers in parentheses indicate the number of measurements. Values calculated from our measurements (M) are shown as the mean $\pm$ maximum possible error ($\delta M = |(\partial M / \partial V_s) \delta V_s| + |(\partial M / \partial V_{\text{ATP}}) \delta V_{\text{ATP}}|$).

* ATPase activity of each myosin molecule during sarcomere shortening was obtained as $V_{\text{ATP}} = V_s \times (W/C) \times 2L_0 / (L_0 + L)$, where V_s is ATPase activity of sarcomere shown as mol ADP per g sarcomere per s; C , myosin content (by weight) of a sarcomere; W , relative molecular mass of myosin (4.8×10^5 , ref. 28); L , length of the overlap region between thin and thick (crossbridges) filaments per half-sarcomere before shortening; L_0 , the length at full overlap of thick and thin filaments. ATPase activity in the non-overlap region (in the relaxed state) was neglected because it was expected to be >20 times smaller than that in the overlap region during shortening. The average values of L_0 and L of sarcomeres used here were 2.3 and 1.1 μm , respectively. C was calculated to be 0.35 by comparing the area of the myosin heavy chain of the sarcomere with that of purified myosin, the weight of which was found according to Arata *et al.*²⁹, on SDS gels.

† The sliding distance of thin filaments during one ATP cycle (lower limit) was obtained according to the equation shown in the text from the sliding velocity (V_s) and the ATPase activity (V_{ATP}). The average number of myosin molecules in half a thick filament overlapping with thin filaments during sliding, N_m , was obtained as $N_m = N_m \times (L_0 + L) / 2L_0$ ($= 640 \times (2.3 + 1.1) / 4.6 = 470$). The number of myosin molecules in half a thick filament, N_m , was obtained as $N_m = (L_0 / P_m) \times n$ where P_m is the myosin subunit repeat (14.3 nm; Namba *et al.*²²); and n , number of myosin molecules per repeat ($= 4$; Wakabayashi^{30,33}). The value of n was also determined to be ~ 4 (3.8–4.3) by SDS polyacrylamide gel electrophoresis according to Tregar and Squire³¹.

Fig. 2 Sequential fluorescence micrographs of a PDTRM-labelled sarcomere without Z-lines during shortening at 5°C. Times (t) are shown in s. Scale bar, 5 μ m. Shortening was initiated by rapidly adding ATP solution from a small pipette at $t = 0$ s to the suspension of sarcomeres on a glass slide enclosed with a bank of glue. The bathing solution (rigor + 0.2 mM CaCl_2) contained 0.2% β -mercaptoethanol to suppress photobleaching. At $t \geq 0.5$ s only a small spot, probably the overlap region, could be seen at the set level of brightness; the image of the ends of filaments became too vague to be visualized. Sample temperature was controlled by attaching a metal rod connected to a bath cooler to the stage of the inverted microscope.

the measurement of shortening velocity. The ATPase activity during shortening at 5°C was 1.0 ± 0.3 mol ADP per mol myosin s^{-1} at 2 mM ATP and decreased to 0.13 ± 0.02 mol ADP per mol myosin s^{-1} after completion of the shortening.

The average sliding distance of a thin filament induced by hydrolysis of 1 mol ATP was calculated from the sliding velocity of the thin filament and the ATPase activity during sliding. The average number of myosin molecules in half a thick filament overlapped with the thin filaments during the shortening, $\bar{N}_m$, is 470 (see Table 1). The ATPase activity during the sliding, V_{ATP} , is 1 s^{-1} at 5°C (Table 1) and the ratio of thin to thick filaments, r , is 6 (ref. 22). Therefore, the number of ATP cycles on one thin filament per s, N_{ATP} , was calculated as $N_{\text{ATP}} = (\bar{N}_m \times V_{\text{ATP}})/r = (470 \times 1 \text{ s}^{-1})/6 = 78 \text{ s}^{-1}$. The sliding distance of the thin filament during one ATP cycle, M , is calculated as $M = V_s/N_{\text{ATP}} = 4.7$ (or 5.3) $\mu\text{m s}^{-1}/78 \text{ s}^{-1} = 600$ (or 680) Å assuming that the ATP cycles occur in turn without overlapping. This value should be the lower limit because the ATP cycles sometimes occur simultaneously, in which case M would become larger. When the temperature was increased to 15°C, a similar high value of M was obtained (Table 1). Thus, the sliding distance of the thin filament induced by the myosin crossbridge during one ATP hydrolysis cycle in the unloaded

Fig. 3 Time course of shortening, light-scattering intensity and ADP liberation during contraction of single sarcomeres without Z-lines.

Methods. Closed circles, extent of shortening observed directly by an inverted fluorescence microscope (see Fig. 2). Ordinate, width between the tops of thin filaments on both sides of the sarcomere (H-band). After these filaments had overlapped, their width was measured between their tail ends and shown as negative values. Solid line, intensity of light scattering from a suspension of single sarcomeres at 90° and $\lambda = 460 \text{ nm}$. The light-scattering intensity increased following an exponential equation consisting of two time constants and then decreased by >10 times slower than the fastest phase (not shown). Assuming that the fastest component of the increase in the light-scattering intensity arose from an increase in the overlap between thin and thick filaments at the A-band and the second from the overlap between the thin filaments from the two opposite sides, the sliding velocity of thin filaments was calculated as $V = (\frac{1}{2}l)/\tau_1 = (\frac{1}{2} \times 2.3 (\pm 0.2) \mu\text{m})/0.22 \text{ s} = 5.2 (\pm 0.5) \mu\text{m s}^{-1}$, where τ_1 is the fastest time constant and l the width of the H-band. l was measured with a fluorescence microscope after labelling with PDTRM. The suspension of sarcomeres was rapidly mixed with ATP and the time course of change in light intensity measured with a stopped-flow spectrophotometer (Union Giken RA-401). Open circles, ADP liberation, measured by the method of Arata *et al.*¹⁸. The ATPase reaction was initiated by rapidly adding a small amount of concentrated ATP solution to the 20 mg ml^{-1} suspension of sarcomeres in rigor solution containing 0.2 mM CaCl_2 , vigorously stirred and stopped by adding HCl (final concentration 0.3 M). ATP and HCl solutions were added using a small syringe connected to an electric solenoid. The ATPase reaction of the sarcomeres (width of H-band = $2.3 \pm 0.2 \mu\text{m}$) was coupled with 15 mg ml^{-1} pyruvate kinase and 2 mM phosphoenolpyruvate to regenerate ATP. The ATPase activity was determined from the rate of pyruvate liberation, measured by the method of Reynarn *et al.*³⁶. The maximum activity of pyruvate kinase (Sigma) was $50 \mu\text{mol mg}^{-1} \text{ min}^{-1}$ in rigor solution at 5°C. When the ATPase activity of sarcomeres of 20 mg ml^{-1} is $20 \mu\text{M s}^{-1}$ (1.4 per mol ADP per mol myosin per s, see Table 1), the lag between the ATP hydrolysis and ATP regeneration reactions in the presence of 15 mg pyruvate kinase per ml is estimated to be only 0.015 s, taking into account that the Michaelis constant of ADP for pyruvate kinase is 0.2 mM³⁶. The protein concentration of the sarcomere was measured by the biuret method and the absorbance at 280 nm was determined after treatment with 1 M NaOH for 24 h at 20°C (ref. 37). All experiments were performed at 5°C.

condition is much longer than the size of the power stroke of the crossbridge, 80 Å deduced from studies on isometric tension transients of muscle (ref. 15).

Because the Reynolds number (inertial force/viscous force) is extremely small for the movement of the thin filament ($\sim 10^{-5}$) or the relaxation time of the velocity of the thin filament after removal of the external force is $<1 \text{ ns}$ ($= m/\zeta = Dm/kT = (10^{-8} \text{ cm}^2 \text{ s}^{-1} \times 10^{-16} \text{ g})/(1.38 \times 10^{-23} \text{ J K}^{-1} \times 300 \text{ K}) = 10^{-10} \text{ s}$, where m is the mass of the thin filament; ζ , the friction constant; D , translational diffusion constant; k , Boltzmann constant; and T , temperature)²³, the movement of the thin filament induced by the myosin crossbridge decays immediately ($<1 \text{ ns}$) after its detachment and the thin filament cannot be moved by an inertial force. The possibility of the movement of several other filaments

hydrodynamically induced by the movement of a thin filament is expected to be very low for two reasons; first, the myosin heads and filament backbone that occupy most of the space in the sarcomere^{22,24} are expected to almost completely abolish the flow of the solution; second, even if the flow of solution is induced, it would almost be abolished because the directions of the flow from two sides of the sarcomere oppose each other. It is also unlikely that the high sliding velocity of the thin filaments in the sarcomere results from electrostatic interactions between them, as increasing the concentration of free Mg^{2+} from 1 to 7 mM did not increase the shortening velocity, although the attractive force among the thin filaments should be stronger at higher concentration of divalent cations²⁵. In fact the shortening velocity decreased by 10% at 100 mM KCl and 30% at 50 mM KCl. Furthermore, the fact that the elastic modulus of thin filaments obtained from analysis of their thermal bending motion in a myosin-free ghost fibre²⁶ is almost the same as that when they are independent in solution¹⁷ strongly suggests that the electrostatic interaction among thin filaments in the sarcomere is very weak.

How can such a long sliding distance of the thin filament per one ATP hydrolysis cycle be reconciled with other measurements? One possibility is that more crossbridge than ATP hydrolysis cycles occur during a transient phase after the start of unloaded shortening¹¹⁻¹³ or during steady state unloaded shortening^{8-10,27}. If there are six or more crossbridge cycles per ATP cycle, the sliding distance obtained here would be similar to that deduced from mechanical studies, 80 Å (ref. 15). The experimental data (Table 1) showed that the number of ATP hydrolysis cycles during the shortening period was about a quarter of the total number of myosin heads. Therefore, it is possible that only a fraction of crossbridges complete the ATP hydrolysis cycle during the shortening period itself. It is unlikely, however, that many of the remaining crossbridges could do work during shortening and hydrolyse ATP after shortening, because the ADP release after shortening is small (Fig. 3).

Another possibility is that when a crossbridge hydrolyses an ATP molecule and produces thin filament sliding, some free energy of hydrolysis is transferred passively to another crossbridge attached to the thin filament; that is, the first crossbridge does work on a second. Then, the second crossbridge produces sliding of the thin filament and again does work on a third. Such a cycle would occur repeatedly during one ATP hydrolysis cycle. This kind of mechanism, however, would require a very regular and directional order of crossbridge attachment-detachment cycles on the thin filament, so that the possibility may not be completely excluded but seems unlikely.

We believe a more straightforward interpretation of our results is that the range of movement over which myosin crossbridge can attach to the actin filament during one ATP hydrolysis cycle under an unloaded condition is at least 600 Å.

We thank Professor K. Maruyama and Drs A. Inoue, K. Wakabayashi and E. Prochniewicz-Nakayama for helpful discussions. We also thank Professors Th. Wieland for providing PDTMR and T. Masaki for suggesting the use of CANP.

Alterations of the *hprt* gene in human *in vivo*-derived 6-thioguanine-resistant T lymphocytes

Richard J. Albertini*‡, J. Patrick O'Neill*‡, Janice A. Nicklas*†, Nicholas H. Heintz† & Philip C. Kelleher*

Departments of *Medicine and †Pathology and ‡Vermont Regional Cancer Center, University of Vermont College of Medicine, Burlington, Vermont 05405, USA

Investigations into the extent and significance of somatic gene mutations occurring *in vivo* in humans have been hampered by the lack of a means of unambiguously defining the mutational origin of *in vivo*-derived variant cells. Several years ago we proposed that 6-thioguanine-resistant T lymphocytes, present at low frequencies in human peripheral blood, might be useful markers of *in vivo* somatic mutation^{1,2}. We and others have since described methods for the isolation and study of these unusual cells³⁻⁵. The thioguanine-resistant T cells stably lack hypoxanthine-guanine phosphoribosyltransferase (HPRT) activity, suggesting that they are somatic equivalents in normal individuals to cells from individuals with the X-chromosomal *hprt* Lesch-Nyhan germinal mutation^{6,7}. We now report that *in vivo*-derived thioguanine-resistant T-cell colonies from a single normal individual show a variety of *hprt* structural alterations, as determined by Southern blot analysis. This finding demonstrates unequivocally that these cells are genetic mutants and validates their use for fundamental and applied mutational studies in humans.

Human T cells were obtained from a healthy male donor and colonies were isolated from a clonal assay, as described by Albertini *et al.*³. Briefly, lectin-activated lymphocytes, mixed with T-cell growth factor and feeder cells, were inoculated into the wells of microtitre plates in the absence or presence of 10^{-5} M 6-thioguanine (6-TG). An average of 2 or 10^5 cells per well was inoculated into non-selected wells or 6-TG-selected wells, respectively. After 16 days, 118 of 960 non-selected wells and 24 of 960 6-TG-containing wells showed growing colonies. Cloning efficiencies, calculated by the Poisson relationship $P_0 = e^{-x}$ (where P_0 is the frequency of negative wells and x the average number of cells per well), were 6.6% and 0.025×10^{-5} in the absence and presence of thioguanine, respectively, yielding a 6-TG-resistant mutant frequency of 3.8×10^{-6} .

Twelve unselected (wild type) and 24 thioguanine-selected (mutant) colonies were isolated and subcultured; 9 unselected and 15 thioguanine-selected colonies achieved total cell numbers of $50-100 \times 10^6$ cells. All cells were positive for the surface marker T11, confirming their T-cell identities. HPRT enzyme activity⁸ in the nine unselected colonies ranged from 30 to 50 pmol inosine monophosphate produced per min per extract of 10^6 cells; $<10\%$ HPRT activity was detected in the 15 6-TG-selected colonies.

Fig. 1 Southern blots of DNA isolated from 4 (A2, A3, B2, B5) wild-type (wt) and 11 (C5, D2, D5, D6, E1, E2, E3, E5, E6, F3, F4) 6-TG-resistant mutant (M) T-cell colonies isolated from one individual and probed with a full-length *hprt* cDNA probe (pHPT31 insert⁹, given by Dr C. T. Caskey). The *hprt* insert of 947 bp contains at least 100 bp of sequence 5' to the initiation codon, the entire coding sequence and ~200 bp of the 3'-untranslated region. **a**, *EcoRI*-digested DNAs. Mutant E6 shows loss of hybridization to an 8.0- and an 8.3-kb fragment. **b**, *BamHI*-digested DNAs. Mutant C5 shows a new fragment at 35 kb, with a possible compensatory loss in the 22–25-kb region which is difficult to interpret because two *hprt* fragments and a cross-hybridizing autosomal fragment localize to this region. Mutant E2 shows a new fragment at 19 kb and loss of the 8-kb fragment. Mutant E5 shows loss of all fragments except the 25-kb autosomal fragment; however, this lane was underloaded. Mutant E6 has definitely lost hybridization to all four *hprt* fragments, although the 25-kb autosomal fragment remains. (Ethidium bromide staining and use of another, non-*hprt*-related probe demonstrated a full aliquot of DNA in all lanes except E5, clearly eliminating underloading as an explanation for fragment losses in E6).

Methods. To isolate the DNA, 15–20 × 10⁶ frozen cells for each colony were washed and resuspended in 1 ml T₁₀E₁ (10 mM Tris, 1 mM EDTA pH 8.0), then 4 ml TENS (25 mM Tris-HCl pH 8, 100 mM NaCl, 10 mM EDTA, 0.6% SDS) was added and the solution heated to 65 °C for 15 min. Proteinase K (0.5 mg) was added, and the mixture incubated at 37 °C overnight, then an additional 0.25 mg of proteinase K was added and digestion was continued for 3 h. The resulting solution was phenol-extracted twice, followed by chloroform/isoamyl alcohol (24:1) extraction, then ethanol precipitation and resuspension in T₁₀E₁. For the Southern blots, ~7.5 µg per lane of genomic DNA was digested with restriction enzymes, fractionated on a 0.7% agarose gel in TAE (40 mM Tris-acetate, 2 mM EDTA) buffer and transferred to nitrocellulose filters (Schleicher & Schuell). Prehybridization was for 5–16 h at 42 °C in Stark's solution¹², then 1–1.5 × 10⁶ c.p.m. ml⁻¹ of oligonucleotide-primed ³²P-labelled *hprt* insert was added and incubation continued at 42 °C for 16 h. Washing consisted of two 10-min washes in 2 × SSC, 0.1% SDS at room temperature and two 1-h washes in 0.1 × SSC, 0.1% SDS, the first at 50 °C and the second at 60 °C. Autoradiography was performed at –80 °C with Kodak XAR-5 film and Dupont lightning plus screens for 3 days.

Southern blot analysis was used to determine alterations of the DNA in the *hprt* genes of the 6-TG-resistant colonies. Genomic DNA of 4 wild type and 11 mutant colonies was isolated from frozen samples of 15–20 × 10⁶ cells. The DNA, cleaved with *EcoRI*, *HindIII*, *BamHI* or *MspI*, was probed with a 947-base pair (bp) full-length *hprt* complementary DNA clone⁹. This *hprt* cDNA hybridizes with four or five restriction fragments in genomic DNA, representing exons of the X-linked *hprt* gene, and also cross-hybridizes with three to four restriction fragments whose sequences have been localized on chromosomes 3, 5 and 11 (refs 10, 11).

On the *EcoRI* Southern blot (Fig. 1a), mutant E6 demonstrates a loss of probe hybridization to two fragments that migrate at 8.0 and 8.3 kilobases (kb) in the wild-type DNA. On the *BamHI* blot (Fig. 1b), mutants C5 and E2 show novel large fragments and E2 has also lost probe hybridization to a fragment at 8 kb. An *MspI* blot (Fig. 2) reveals a striking loss of fragment hybridization for mutant E6.

Using characterized subfragments of the full-length *hprt* cDNA clone, Caskey and co-workers mapped the 5'-untranslated, 5' coding, 3' coding and 3'-untranslated regions to specific restriction fragments generated by several endonucleases¹¹. Thus, it is possible to determine where alterations have occurred in the *hprt* DNA sequences of somatic 6-TG-resistant mutants by comparing the fragments absent in the mutants with the known restriction-fragment maps of the *hprt* gene^{10,11}. For the *BamHI*, *EcoRI* and *HindIII* blots, all of the missing or changed fragments reported here represent the X-linked *hprt* gene and not the autosomal cross-hybridizing sequences. However, as information on the chromosomal location and gene mapping of the *MspI* fragments has not yet been reported, definite statements on the gene alterations represented by changes in restriction fragment patterns with this endonuclease cannot be made.

Overall (see Table 1), and including data from other blots (not shown), four of the mutant colonies (D2, D6, E1 and E3) showed no restriction fragment alterations, compared with the four wild-type colonies (which, as expected, had identical patterns). Mutant E2 showed a reciprocal gain of hybridization to a novel fragment and a loss of hybridization to a wild-type *BamHI* fragment representing the 5' end of the gene. Mutant E6 demonstrated changes with all four of the enzymes tested, suggesting a deletion involving a considerable portion of the 3' end of the gene. Mutant C5 showed changes with two enzymes. *MspI* showed a gain of a large fragment, with corresponding loss of a small fragment; *BamHI* showed a gain of a 35-kb fragment with a possible loss of a 22–25-kb fragment (the migration of several fragments in the 22–25-kb region makes interpretation difficult). The blots for the remaining four mutants (D5, E5, F3 and F4) were difficult to score. Two mutants (D5 and F3) showed weak hybridization to a new 1.95-kb *MspI* fragment, perhaps as a consequence of incomplete digestion. For E5 and F4, there was insufficient DNA to test more than one or two enzymes.

The 11 6-TG-resistant mutant colonies described here were developed from progenitor mutant cells that arose *in vivo* in a single normal adult male. Thus, the different mutations do not represent a polymorphism among individuals but, rather, indicate that various molecular lesions can give rise to somatic mutations at this single locus within an individual.

Yang *et al.* demonstrates *hprt* DNA changes in 5 of 28 independent germinal Lesch-Nyhan mutations after digestion with four endonucleases¹⁰. By comparison, 3 of the 11 somatic mutants studied here (C5, E2 and E6) show obvious alterations in the *hprt* structural gene. Thus, at least four independent mutational events have occurred. However, this is certainly an underestimate for at least two reasons. First, two other colonies,

Fig. 2 Southern blot of DNA from one wild type (B5) and five thioguanine-resistant mutant (C5, D5, D6, E6, F3) colonies digested with *MspI* and probed with the *hprt* insert from pHPT31. Mutant C5 shows hybridization to a novel fragment at 16.5 kb and reciprocal loss of the 9.4-kb fragment. Mutant E6 shows loss of hybridization to the 9.4-, 3.8-, 1.8- and 1.35-kb fragments. The new faint fragments at 2.0 kb for D5 and F3 may be a result of partial digestion and are not considered to be new fragments. (Methods as for Fig. 1).

E5 and F4, show possible structural changes with one or more of the four endonucleases used. Analysis with additional endonucleases will probably define more colonies having detectable DNA alterations. Second, we do not know what proportion of the other mutants not showing gross rearrangements were a result of small deletions, duplications or point mutations. Further study is necessary to define the number of independent mutational events responsible for this collection of thioguanine-resistant mutants. However, the results presented here do constitute unequivocal evidence for the mutational origin of the thioguanine-resistant T cells that arise *in vivo* in the normal human.

A hybrid recognition sequence in a recombinant restriction enzyme and the evolution of DNA sequence specificity

Valakunja Nagaraja, John C. W. Shepherd & Thomas A. Bickle*

Microbiology Department, Biozentrum, University of Basel, Klingelbergstrasse 70, CH-4056 Basel, Switzerland

Early attempts to generate new restriction specificities by recombination between allelic restriction-modification systems have been unsuccessful¹. Bullas *et al.*² succeeded in isolating a new specificity, SQ, in *Salmonella* that they interpreted as being the result of a recombination event between the parental strains, *Salmonella typhimurium* and *S. potsdam*, which encode the SB and SP restriction systems, respectively. This interpretation has recently been confirmed by DNA heteroduplex studies with the SB, SP and SQ structural genes³. We have determined the DNA sequences recognized by the SB and SP enzymes⁴ and found that, like all type I restriction sequences, they are split into two specific domains by a spacer of nonspecific sequence that, for both SB and SP, is 6 base pairs (bp) long. We have now determined the sequence recognized by the recombinant SQ enzyme and find that it is a hybrid between the SB and SP sequences, containing one specific domain from each parental strain. This result implies that each of the two specific domains is recognized by a physically distinct part of the enzyme.

The SQ enzyme was purified from the strain L4004 (ref. 2) by methods used previously for SB and SP⁴. Its recognition sequence was determined using a computer-aided strategy described in detail elsewhere⁴. The method depends on the fact that type I restriction enzymes are also modification methylases and thus can be used to introduce radioactive methyl groups into their recognition sites in sequenced DNA molecules. The radioactive label is then mapped to small regions of the DNA by restriction analysis and fluorography and computer analysis is used to find DNA sequences common to all labelled regions and absent from all others.

We screened various different sequenced DNA molecules for the presence of SQ sites by *in vitro* methylation with [³H-Me]-S-adenosyl methionine. DNA molecules that had no SQ sites were pBR322, pBR325, pSHI44, pFR100, ØX174, G4, M13 and simian virus 40. Phage λ DNA, which has been reported not to be restricted by the SQ system², was a substrate for the enzyme. In our hands SQ does restrict, with plating efficiencies ranging from 10⁻¹ to 10⁻² in different experiments. Mapping experiments showed that λ DNA contains a single site for the enzyme, which

* To whom correspondence should be addressed.

Fig. 1 Mapping of the SQ site in phage λ DNA. The DNA was methylated with purified SQ enzyme and [$^3\text{H-Me}$]-S-adenosyl methionine (Amersham, 62–74 Ci mmol $^{-1}$) as described earlier⁴. The labelled DNA was then cleaved with different type II restriction enzymes and the fragments were separated on either a 1% agarose gel (a) or an 8% polyacrylamide gel (b). The gels were photographed after staining with ethidium bromide and then fluorographed. a, Mapping of the SQ site with enzymes that cut the DNA infrequently. The left panel shows the stained gel, the right panel the fluorogram. The enzymes used and the extent of the labelled fragments are: lane 1, *EcoRI*, 1–21,226; lane 2, *AccI*, 1–2,190; lane 3, *AvaI*, 1–4,720; lane 4, *HindIII*, 1–23,120. b, Fine mapping of the site and confirmation of the sequence. Only the fluorogram is shown. Lane 1, *HaeIII*, 403–469; lane 2, *HaeIII* + *RsaI*, the same fragment is labelled as in lane 1, even though *RsaI* has a site at position 439; lane 3, *BstNI* + *HaeIII*, 425–469; lane 4, *BglII* + *TaqI*, 415–451; lane 5, *BstNI* + *FnuDII*, 425–459. We conclude that a SQ site is present between positions 425 and 451.

Fig. 2 The recognition sequences of SP, SB and SQ. Homologies between the sequences are indicated by bars.

we first mapped to the left 2,190 bp of the DNA molecule (Fig. 1a) and then, using combinations of fine-cutting enzymes, to a 26-bp stretch extending from positions 425 to 451 of the λ DNA sequence⁵ (Fig. 1b). Another SQ site was found and mapped to a small region of the yeast *PHO5* gene⁶ (not shown). The two regions that contained SQ sites, together with all the sequences that did not, were subjected to computer analysis as described above. Most sequences were taken from the DNA sequence databank of the European Molecular Biology Laboratory (EMBL). This search failed to find a non-degenerate sequence that could be a candidate for the SQ recognition site, but further searches found a single sequence with one degeneracy that fitted the data 5'-AACNNNNNNRTACG-3', where N is any nucleotide and R is either purine. The experiment shown in Fig. 1b, lanes 1 and 2, confirms this sequence. In phage λ , G is present in the position indicated as R and the resulting 5'-GTAC-3' is an *RsaI* recognition site. Figure 1 shows that *RsaI* does not cut this site in SQ-modified DNA, indicating that SQ has methylated the DNA within the site.

We then searched the EMBL DNA sequence databank for other DNA molecules containing the putative SQ site and variants of it and found that the plasmids p3201 (ref. 7) and *colE1* (ref. 8), phage T7 DNA⁹ and the yeast *CYTcI* (ref. 10) gene were suitable for further analysis. The SQ sites in all of these DNA molecules were labelled and mapped (not shown) and the results are summarized in Table 1. One further degeneracy in the sequence was found and the SQ recognition site is 5'-AACNNNNNNRTAYG-3', where Y can be either pyrimidine. Sequences that had pyrimidines in the position marked by R or purines in the position marked by Y were not

Table 1 Compilation of SQ recognition sequences

Consensus:		AACNNNNNNRTAYG

substrates for the enzyme. All four nucleotides can be found flanking the sequence and at all positions of the nonspecific spacer (Table 1).

Figure 2 compares the recognition sequence of SQ with those of its parents, SB and SP. SQ has the AAC domain of SP and the RTAYG pentanucleotide domain of SB. It is clear that the recombination event that generated SQ took place within the region encoding the part of the polypeptide that is involved in sequence recognition.

The allelic type I restriction enzymes found in *Escherichia coli* and *Salmonella* spp. are complex enzymes, and DNA recognition is a function of just one of their subunits, the product of the *hdsS* gene (reviewed in ref. 11). Several *hdsS* genes have been sequenced¹² and the sequences are surprisingly non-homologous, only two short regions, one in the middle of the gene and the other at the 3' end, being highly conserved. The recombination that yielded SQ took place in the central conserved region³. It is not known whether the parts of the polypeptide that bind the recognition sequence are encoded by this region or by the nonconserved sequences on either side.

Recombination between *hdsS* genes has the potential for generating any combination of specific sequence domains and thus of creating new sequence specificities. There is some indication that this may have happened naturally in the past. For example, *EcoK*, SP and SQ all share a common AAC domain while GAG is common to both *EcoB* and SB. One response of bacteriophages to the presence of restriction enzymes in their hosts is to mutate the recognition sites in the phage genomes, making them resistant to restriction^{13,14}. It is therefore advantageous for the host to be able to change the recognition specificity of its restriction system from time to time.

We thank P. G. Baas, A. Hinnen, H. S. Jansz, C. Sengstag, D. Sherratt, F. W. Studier and A. P. G. M. Van Loom for gifts of phages and plasmids, C. Price for helpful comments on the manuscript and T. Pripfl for help with the experiments. This work would not have been possible without access to the EMBL DNA sequence databank, and was supported by grants from the Swiss NSF.

diamonds, and... ...laser machining

D. Drukker & Zn. N.V. of Amsterdam, Holland, are manufacturers of high precision diamond components. These include heat sinks for semiconductor lasers and microwave diodes, space-qualified infrared-transmissive optical components, bolometer substrates, high pressure anvils, and a wide variety of ultrasharp cutting instruments.

To make these products Drukker developed expertise in computer controlled laser machining of diamond, and is able to produce complex shapes to narrow tolerances in this and other hard materials. The SEM picture shows a laser machined diamond helix (patent applied for), part of an experimental travelling wave tube development project.

Drukker offers laser machining services, not only for diamond, but for a range of other hard materials also. If you need to laser cut small components, difficult materials, complex shapes... please contact us. And, of course, if you need anything whatsoever made of diamond!

diamond, a gem of a material for science & industry

The laser — hero or villain?

from Bridget Marx

Although too often associated in people's minds with star wars weaponry the laser has become an invaluable tool in many varied and peaceful applications.

IN the early days the laser, for Light Amplification by Stimulated Emission of Radiation, was dubbed 'a solution looking for a problem', but in the last quarter of a century lasers have found application in areas as diverse as materials processing and the treatment of cancer.

The medical application of lasers is now in fact a major industry—out of an estimated total commercial laser market of about \$400 million, at least one quarter is connected with medical and surgical applications. This market is growing at a rate of more than 30% per year and has become such a significant factor for the manufacturers of lasers that several companies have actually been bought out by medical conglomerates.

Laser surgery

The laser was first demonstrated in 1960 by Theodore Maiman at the Hughes Research Laboratories in California, and the first 'medical' application came when Maiman's ruby laser was being used in animals' eyes, as a source for photocoagulation and by 1962 human patients were being treated. As new lasers became available these were quickly tried out in the medical field. The argon ion laser was first considered in 1965, the clinical trials were started in 1969 and the first commercial systems became available in 1971. The argon laser has proved a lot more successful for the treatment of vascular diseases of the retina than the original ruby systems and there are now many thousands of medical argon lasers worldwide. At the time of writing lasers in routine use in hospitals include the argon ion laser, the carbon dioxide laser, the Nd:YAG laser and, to a lesser extent, the krypton ion laser. Those at present in the early stages of development include the excimer,

gold vapour and copper vapour lasers.

The laser is in many ways ideally suited to medical applications, providing as it does a light source that is powerful enough to destroy the target tissue yet is controllable in terms of power, spot size and wavelength. The light can be easily and efficiently taken to the required site either directly or by optical fibre. These advantages led to the rapid development of laser surgery in dermatology, ophthalmology and gynaecology. Other exciting areas are also opening up, such as photoradiation therapy for the treatment of cancer, laser recanalization of clogged arteries, laser welding of soft tissues, and even laser acupuncture for pain relief.

Diagnostics

The direct surgical use of lasers is not the only clinical application of lasers, and after photocoagulation, the 'surgical' application which accounts for 40% of all water-cooled lasers in use, the makers of cytofluorescence equipment are among the biggest consumers of water-cooled ion lasers, accounting for a further 14% of the market. Lasers allow biological specimens to be analysed for their cell content and the different cells to be sorted into different containers depending on their light scattering characteristics. This method of detecting cancer cells is very straightforward and cell-sorting equipment is to be found in many hospital laboratories.

Non-medical

The largest market for lasers is still in academic and industrial research and development: nearly \$100 million out of the total \$400 million. A traditional area of pure research is spectroscopy, and other growth areas are laser Doppler velocimetry and holography. Holography

these days is used not just for making pretty pictures, but also for making non-forgeable security passes and credit cards. And even spectroscopy has left the realms of pure research as we move into the age of laser isotope separation. (Laser isotope separation accounts for more than one eighth of the total CW dye laser market each year.) There is also a large part of the world's laser research effort concentrated in the field of optical-fibre communications, so that in the future telephone messages will not be relayed by an electrical signal along a wire but will be carried by a modulation of a laser beam that is being conducted along an optical fibre.

Popularization

Apart from these scientific applications there is a plethora of relatively 'low-tech' areas where lasers are carving out a niche. The entertainment industry is a market sector worth several millions of dollars each year. Laser light shows are quite commonplace these days in discotheques or at big public gatherings, as demonstrated during the 1984 Olympic Games in Los Angeles. There are also schemes using lasers to project television images onto a large screen with enough brilliance to be seen in daylight. And there are markets that use large volumes of low-cost lasers. In the entertainment industry the home video and audio disk systems come into this category. There are also laser printers and bar-code reading scanners at supermarket checkouts: these account for about 10% of the laser market, using approximately 100,000 small lasers a year.

In heavier industries too, lasers are gaining ground. Highpower infrared lasers are used for cutting, drilling and welding in laser machine tools. Ultraviolet excimer lasers are used in photolithography and other developmental techniques in the semiconductor industry.

So how will history judge the laser as it emerges from its formative years: Hero or villain? It has proved its worth in the areas of scientific research and manufacturing. It is capable of many medical feats, from miracle cure to routine surgery. President Reagan's Strategic Defense Initiative is based on the hope that it has an equally destructive side to its nature. □

The largest market area for lasers is still research and development. One application in which basic physics is tested is shown here. In this exotic application an argon ion laser is used to illuminate a long baseline interferometer for the detection of gravitational radiation. Interferometers with baselines of many kilometres are planned. The photograph shows an early prototype Michelson interferometer with a relatively short baseline. (Photo courtesy of Glasgow University.)

Bridget Marx is UK Sales Manager of the Laser Products Division of Coherent (UK) Ltd, Cambridge Science Park, Milton Road, Cambridge CB4 4BH, UK.

Lasers in commercial applications

A user-group based at Culham gives access to high-power lasers, and laser Raman microscopy is becoming established.

- A series of five reports from the Laser Analytics Division of Spectra-Physics should be of interest to all those using mass spectroscopy for the determination of trace moisture in hermetically-sealed integrated circuit packages. The reports show that the results of the infrared testing of IC packages sealed under controlled moisture conditions exhibit significant gaseous and absorbed moisture discrepancies when compared to less-accurate mass spectroscopy. Titles of the five are: (1) 'Water Vapor Measurements in IC Packages Using an IR Diode Laser'; (2) 'Trace Analysis of Moisture in IC Packages Using Derivative Diode Laser Spectroscopy'; (3) 'Laser Spectrometric Determination of Moisture in IC Packages'; (4) 'Dynamic Measurement of the Water Vapor Content of IC Packages Using Derivative IR Diode Laser Spectroscopy'; (5) 'Trace Analysis of Microvolume Gas Samples Using IR Spectroscopy Moisture in IC Packages'.

Reader Service No. 100.

The new Melles Griot laser is an alternative to solid-state systems.

- A new helium/neon laser with infrared output at $1.523 \mu\text{m}$ is now available from Melles Griot. The new laser matches the output of solid-state laser diodes, without the inherent problems, and should find applications in data transmission, intrusion alarms, target designation, range finding and security systems. Current models offer 0.25, 0.5 or 1.00 milliwatts of TEM₀₀ single longitudinal mode collimated coherent output. This output matches the minimum attenuation in the new high performance OVD fibres, falls in the middle of a clear atmospheric window, corresponds to the sensitivity peak of InGaAs detectors and is classified 'eye safe' by the US Bureau of Radiological Health. These $1.5 \mu\text{m}$ He/Ne lasers are constructed with zero-leak hardseals for longevity, and feature a patented symmetrical cold-cathode for stability. The instruments are based on the same design and manufacturing techniques as the company's established 632.8nm range.

Reader Service No. 101.

These notes are based on information provided by the manufacturers. To obtain further details about these products use the reader service card bound inside the journal.

- The Hybond Laser Spotlight Bonder, specially developed for wire-bonding, features enhanced accuracy provided by a laser spotlight which enables the work piece to be positioned quickly and with great precision. An integral 'soft-touch' ramping force generator protects the work piece against thermal shock. Precise control of position is achieved by a combination of easy-to-use adjustable controls for search, bond and loop height, with a motorized z function for true vertical movement. Quick visual reference and ease of fine adjustment is provided by the 'Paramagraph' controls. In the United Kingdom the bonder is available from Intertrade Scientific of Milton Keynes.

Reader Service No. 102.

- The Leybold Heraeus LAMMA 1000 uses a Nd:YAG laser to provide approximately 2mJ of light energy in 15 ns focused to $1 \mu\text{m}$ spot size. This laser power is used to ionize a micro-volume of the sample which is held on a precision x-y-z table in the sample chamber. The ions formed are then accelerated into a time of flight drift tube and are mass resolved. The ion detector at the end of the drift tube has a copper-beryllium dynode electron multiplier giving an amplification of better than 10^6 . The ease of putting a sample into the instrument with the minimum of sample preparation makes this instrument particularly useful for analysing small bulk samples. The lateral resolution allows the determination of distribution of atomic or molecular species. It is also possible to trace stable isotopes and to do depth profiling with LAMMA. By reducing the laser power, larger ionic fragments are produced for analysis of organic substances. It is possible to obtain positive or negative spectra and masses greater than 1,000 amu can be resolved. LAMMA can detect beryllium, lithium, helium and hydrogen.

Reader Service No. 103.

The LAMMA system from Leybold Heraeus resolves masses greater than 1,000 amu and easily detects beryllium, helium and hydrogen.

- Culham Laboratory's Laser Application Group produces two multi-kilowatt lasers, the CL5 and CL10, together with the associated beam-manipulating and work-handling facilities. Applications include material processing, such as cutting, welding and surface treatment, high power CO₂ laser beam propagation, monitoring and quality control. The Laser Applications Group, which is situated at the UK Atomic Energy Authority's Culham Laboratory, carries out contract research and development on high power laser systems for customers from both industry and government-funded organizations. The group has assembled an extensive range of CO₂ lasers, with output powers from a few watts up to greater than 10kW. A wide variety of beam-manipulating and work-piece handling equipment has also been developed and experience has been gained in the propagation of multi-kilowatt laser beams over distances greater than 50m. Reliable techniques have been developed for materials processing and for analysing the laser beam quality. This expertise enables the Laser Applications Group to offer customers services from a short assessment to the provision of a complete laser-based flexible manufacturing system. Development programmes are undertaken either for individual customers or on a group-sponsored basis. A 'Laser Users' Club' has been formed at Culham to provide the member companies with the necessary knowledge of laser processing technology for them to remain competitive. The Laser Club programme, has been sponsored jointly by eight companies and the Department of Trade and Industry. The Laser Applications Group aims to establish other club activities, particularly with European participation, and these could be directed towards specific industries.

**COHERENT
INNOVATIONS**

► **INNOVA™ breaks through!** **6 watts from a small frame laser.**

The NEW INNOVA 90-6.
Six watts visible on 45 amps,
extended warranty
and more...

The INNOVA 90-6 is a new product designed to meet your request for a reliable, high-powered small frame ion laser. The new 6 watt visible laser runs on an economical 45 amps ... *20% lower electrical power requirement and 20% more output than the competition.*

Visible power up 20%.
UV power up 100%.

The INNOVA 90-6 features 6 watt visible and 400 mw UV to provide the highest guaranteed TEM₀₀ output available in any small frame ion laser. Like all the INNOVA 90 lasers, the 90-6 has a series

INNOVA 90-6 SPECIFICATIONS

regulated power supply. Unlike an SCR power supply, a series-regulated system does not exhibit switching spikes and, therefore, *does not produce line disturbances* negatively affecting your and your colleagues' experiments.

The INNOVA 90-6: The ultimate small frame, high-powered ion laser.

The introduction of the INNOVA 90 has marked a revolution in ion laser technology. But, we have not stopped there. Our R&D efforts have been continuously aimed at improving performance and reliability. This is the reason why today we can offer you a product, the INNOVA 90-6, with the highest power, the *lowest noise and the best proven reliability* in the industry.

Extended warranty... a commitment for success.

We'll do everything in our power to help you succeed. Our level of support is a commitment for success. Constant, thorough and professional support for every Coherent product. Not only do we back the INNOVA 90-6 with our standard 18-month warranty, but we offer you additional *warranty extensions* covering all parts of your laser up to five years total.

For more information, call or write: Coherent Laser Products Division, 3210 Porter Drive, P. O. Box 10321, Palo Alto, CA 94303 (415) 493-2111.

Reader Service No.20

Goodman and Gilman's The Pharmacological Basis of Therapeutics

EDITED BY L. S. GOODMAN, A. G. GILMAN, T. W. RALL AND F. MURAD

* New edition to be published September 1985

* Fully updated

* An essential text and reference work

The seventh edition of this world-renowned textbook of pharmacology, toxicology and therapeutics has undergone a thorough updating of every chapter in respect of the mechanism of action and rational use of older therapeutic agents and the addition of important new drug entities. However, readers of previous editions will find the same good organisation, clarity of writing and authority that have made 'Goodman and Gilman' the standard book in the field.

CONTENTS (MAIN SECTIONS)

General principles; Drugs Acting at Synaptic and Neuroeffector Junctional Sites; Drugs Acting on the Central Nervous System; Autacoids; Drug Therapy of Inflammation; Cardiovascular Drugs; Water, Salts and Ions; Drugs Affecting Renal Function and Electrolyte Metabolism; Drugs Affecting Uterine Motility; Locally Acting Drugs; Chemotherapy of Parasitic Diseases; Chemotherapy of Microbial Diseases; Chemotherapy of Neoplastic Diseases; Drugs Acting on the Blood and the Blood-Forming Organs; Hormones and Hormone Antagonists; The Vitamins; Toxicology; Appendix I – Principles of Prescription Order Writing and Patient Compliance Instruction; Appendix II – Design and Optimisation of Dosage Regimens; Pharmacokinetic Data and Appendix III – Drug Interactions.

SOME OF THE NEW MATERIAL IN THIS EDITION

Critical discussion of important new drug entities – New antihypertensive agents; Antiinflammatory agents; Drugs for ulcer therapy; Antidepressants; Antifungal agents; Antiviral agents; Immunosuppressive agents; Digitalis substitutes; Antiarrhythmic agents; Second-generation sulfonylureas; Neuromuscular blocking agents and anaesthetics; Agents for dissolution of gallstones; New opioid agonists and long-acting antagonists.

New approaches to important therapeutic problems – Proton pump inhibitors, HMG CoA reductase inhibitors, Recombinant DNA technology for production of human proteins and Streptokinase.

A thoroughly revised section on antibiotics including a summary table on "Current Use of Antimicrobial Agents in the Therapy of Infections"; Discussion of new antimicrobial agents.

Extensive revision of sections on: Calcium channel blockers; Benzodiazepines; Drug treatment of hyperlipoproteinemias; Chemotherapy of parasitic diseases; Treatment of psychiatric disorders; Neuroactive peptides; Antiproliferative agents; Prostaglandins and related autacoids; Endorphins, enkephalins and the effects of therapeutic agents; A greatly expanded appendix on pharmacokinetics and an expanded discussion of pharmacodynamics; Thorough discussion of drug interactions and their prevention; Extensive bibliographies.

To be published September 1985

Available in UK, Continental Europe and Africa from your local bookseller, or MACMILLAN ADMINISTRATION, HOUNDMILLS, BASINGSTOKE, HAMPSHIRE RG21 2XS, UK.

Rofin-Sinar's optical spectrum analyser for the range 200–4,700 nm.

• Rofin-Sinar Laser UK Ltd has broadened its range of optical spectrum analysers with the introduction of the Model RSO 6230 spectral processor. The new unit is fully computerized and includes an IEEE and RS232 interface. The system includes a 9-inch computer screen, a keyboard, two 160K, 3½-inch industrial-type floppy disk drives, integrated computer and all controls needed to interface directly to the RSO 6100 series monochromator heads. It can provide the user with a wavelength and amplitude corrected spectrum. A full scan, sampling the spectrum every 0.5nm, takes 1.6 seconds. Alternatively if the spectrum is sampled every 10nm, a complete spectrum can be acquired in 100ms. There are interfaces for a printer, IEEE, RS232 and oscilloscope built into the unit, and a semiautomatic calibration feature provides speed and ease of wavelength calibration. Wavelength accuracy is typically better than 1nm. The spectral range may be covered from 200 to 4,700nm.

Reader Service No. 105.

• High performance photon drag detectors, used for the temporal analysis of high peak power CO₂ laser pulses, are now manufactured by Edinburgh Instruments of Riccarton, Scotland. These detectors are available in two formats for use as either an in-line monitor with 75% transmission, or an end of the line detector. Both types are characterized by the usual well-established properties of photon drags — room temperature operation, very fast response (less than 1ns), high damage threshold, compactness and ease of use. They also offer extra wide-angle access for easy alignment, a stainless steel housing, elimination of photodiode effects at the electrode, an insulated mounting sleeve to significantly reduce the transient noise pick up from TEA lasers and good long-term stability. These detectors have a guaranteed spatial uniformity of $\pm 2\%$ compared with conventional photon drag detectors which typically exhibit a sensitivity at the edge of the face up to 40% higher than at the centre. Both of Edinburgh Instruments' photon drags have a usable aperture of 10 mm and the typical responsivity of the monitor is 180 mV per MW and the detector is typically 200 mV per MW. Damage threshold figures are 20 MW per cm².

Reader Service No. 106.

• Digital delay generators are widely used in pulsed laser timing, fast circuit analysis and fibre optic testing to accurately and repeatably control time. A signal is used to trigger the generator which produces a pair of output pulses, an initial pulse and a delayed pulse. The duration between the two pulses is digitally selectable according to the requirements of the experimenter. The new Model 7695 from Berkeley Nucleonics Corporation has been designed to make gate and delay generation in the sub-nanosecond region not only possible but also highly repeatable. Delays of up to 10ms can be dialled into the unit in 50 ps steps. Until now delays of such short duration have not been possible without problems connected with accuracy, jitter and transition times. The BNC Model 7095 has a guaranteed jitter of less than 25 ps r.m.s. maximum, and an accuracy of ± 0.1 ns on delay generation, up to 9,950 ps. Various options are available including full IEEE 488 compatibility which includes an internal RAM for storing up to sixteen settings. The extremely short delay times attainable with the Model 7095 make it suitable for time of flight experiments, radar simulation, shock-wave physics, chemical kinetics, plasma physics, fibre optics and laser applications.

Beam Scan for the analysis of laser output.

• Oriel Scientific's Beam Scan system is a compact analyser for the comprehensive characterization of the output parameters of lasers and imaged white light sources. Available in several models spanning the 0.1 to 1,000 μ m range, Beam Scan can measure beam size, spatial profile, ellipticity, divergence and collimation. The instrument, which utilizes a moving narrow slit (or pinhole) and a photosensitive detector, continuously samples the energy of a beam incident on it, measuring the intensity profile and relaying, for example, the beam size, at a pre-selected intensity level (for example $1/e^2$) to the front panel LED display. Alternatively this information is available, from an output jack, as a direct analogue signal for display on an oscilloscope. For optical alignment, focal length and image quality checking, both in the visible, and in the non-visually observable infrared, Beam Scan can quantify or track beams from 7.5 μ m to 17mm in diameter. Among its application areas, Beam Scan can be used to characterize fibre optic sources, mode filling and numerical aperture, or compare acousto-optic input and output beam parameters.

LIPOSOMES

REPRODUCIBLE — HOMOGENEOUS —
EXTREMELY RAPID

Our new commercial LIPOSOMAT guarantees rapid (5ml within 60 minutes) preparation of uniformly sized

- UNILAMELLAR OR
- OLIGOLAMELLAR OR EVEN
- MULTILAMELLAR LIPOSOMES

depending on the used experimental conditions. Liposome size is selectable between 25 and ca. 600 nm diameter up to 1000 nm for multilamellar liposomes. Sample volume is normally 5-10ml or up to 200ml if used in combination with an additional instrument. High encapsulation efficiency for hydrophilic and/or lipophilic agents. Lipid concentration can be up to 300 mg/ml. Lipid loss during preparation is extremely low: down to 0.1%.

• New from Labsphere is an infrared integrating sphere for CO₂ laser power measurements which uses a 4-inch diameter water-cooled sphere with diffuse gold coating. The WIS-4000 can be used in conjunction with almost any infrared detector which mounts at a port on the integrating sphere. The high power levels of infrared lasers are attenuated to a 'safe' value within the operating range of the detector and alignment sensitive measurement errors are eliminated. The WIS-4000 can also be mounted at the back mirror of the laser cavity to monitor actual power levels during operation. The WIS-4000 is normally supplied with a gold coating optimized for diffuse reflectance at the CO₂ laser wavelength. However, the sphere may be supplied optimized at other infrared laser lines as well. Accessories for the WIS-4000 include a water-cooled laser target used to reflect the first strike of the laser and a constant temperature recirculating cooler.

Reader Service No. 109.

New from Spectra Physics, a single-mode tunable diode laser.

• The new range of short-cavity lead-suit lasers from the Laser Analytics Division of Spectra Physics provides substantially improved single-mode performance at liquid nitrogen temperature and above. The latest lasers make possible the achievement of single-mode, CW emission from short-cavity mesa-stripe geometry Pb-salt diode lasers in 5, 10 and 30 μm spectral regions. The new devices, with a cavity length of 120 μm exhibit a Fabry-Perot mode separation of 6 cm^{-1} . Exploiting the spectral narrowing of the optical gain characteristics with increasing operating temperature single-mode operation can be obtained over broad current ranges in the 5 and 10 μm spectral regions at liquid nitrogen temperature and above. For the 30 μm lasers, single-mode operation is possible in short-cavity lasers at current values of up to almost twice threshold. Single-mode tunable diode laser (TDL) operation in the mid-infrared spectral region is of great interest in applications such as high-resolution infrared spectroscopy, heterodyne detection, and, in the future, mid-infrared fibre transmission. In addition, operating such lasers at liquid nitrogen temperature and above greatly simplifies the cooling requirements.

Reader Service No. 110.

• A series of Laser Beam Analysers (LBA) manufactured in West Germany by ALL is now available in the United Kingdom. The LBA accurately monitors the spatial distribution of a laser beam intensity in two orthogonal axes. The instruments use a highly reflective molybdenum needle rotating at 50Hz perpendicular to the beam path that reflects a fraction of the beam onto two pyroelectric detectors. The amplitude of the signals from these detectors displayed simultaneously on a dual trace oscilloscope corresponds to the power distribution through the beam. The LBA can handle beam powers from 10W to 20KW, with power densities up to 10 W cm^{-2} . As the power loss of the beam is only 0.8% as it passes through the LBA, the instruments can be used for on-line monitoring of beam profiles during experiments and material processing. The LBA can monitor changes in the mode before they become apparent in the quality of the laser processing. Other applications include measurement of beam divergence and beam focus by movement along the laser beam path.

Reader Service No. 111.

• Laser Raman microscopy is now established as a powerful analytical technique. It provides a means of examining and chemically analysing samples as small as 2 μm in size in a non destructive way. The laser beam, often with a power of less than 100 mW, enters the microscope and is focused on the area of the sample under investigation. The Raman scattered light is collected and enters the spectrometer which then produces the vibrational spectrum of the sample. The technique has proved invaluable for studying optical fibres, semiconductor films, lubricants, corrosion effects, fluid inclusions in geological samples, biological tissues, waste products and polymers. Application notes are available on most of these applications from Glen Creston Instruments.

Reader Service No. 112.

Glen Creston Instruments' laser Raman microscope can analyse samples only 2 μm in size in a non-destructive manner. Applications include study of fluid inclusions in geological samples as well as analysis of biological tissues.

The Littrow-mounted diffraction grating end reflector.

• The Optometrics Group, long established in the field of photonics, has introduced the model LA-1000, the latest in a series of light harnessing instruments. This infrared Laser Attenuator gives researchers greater flexibility in experiments requiring precision attenuation of infrared laser beams. The LA-1000 is primarily designed for linearly polarized lasers, especially CO₂ lasers at 10.6 μm . For unpolarized lasers, it is possible to use two attenuators in series. Also from Optometrics is a new system for wavelength tuning and selection. The output wavelength of a laser can be tuned by turning the Littrow-mounted diffraction grating end reflector about an axis parallel to the grooves. The equation relating wavelength to angle of incidence on the grating is $n\lambda = 2d \sin i$. Using this relationship, one can calibrate a mirror mount to i using a grating as one of the reflectors in the laser cavity. This will narrow the spectral line width of the output in a region around the Littrow wavelength.

Reader Service No. 113.

• Spectra Diode Labs has introduced a new range of 200-mW continuous wave diodes. Claimed to be the most powerful diode lasers commercially available, they should find a niche in such fields as solid-state lasers, and fibre optic power delivery.

Principles of Plasma Electrodynamics. By A.F. ALEXANDROV, L.S. BOGDANKEVICH and A.A. RUKHADZE. Springer-Verlag. 1984. Pp.488. ISBN 3-540-12613-9/10-387-12613-9. DM135.

Quantum Field Theory. By LEWIS H. RYDER. Cambridge University Press. 1985. Pp.443. ISBN 0-521-23764-5. £40, \$74.50.

Seismic Migration: Imaging of Acoustic Energy by Wave Field Extrapolation. By A.J. BERKHOUT. Elsevier. 1984. Pp.274. ISBN 0-444-42431-8. Np.

Simulation for Nuclear Reactor Technology. By D.G. WALTON. Cambridge University Press. 1985. Pp.444. ISBN 0-521-26785-4. £35, \$69.50.

Solitons in Nuclear and Elementary Particle Physics. A. CHODOS, E. HADJIMICHAEL and C. TZE (eds). World Scientific. 1984. Pp.313. ISBN 9971-966-89-1. £39.10.

Space, Time and Causality: An Essay in Natural Philosophy. By J.R. LUCAS. Clarendon. 1984. Pp.206. ISBN 0-19-875057-9. £19.50.

Surface Enhanced Raman Vibrational Studies at Solid/Gas Interfaces. By I. POCKRAND. Springer-Verlag. 1984. Pp.187. ISBN 3-540-13671-1/10-387-13416-6. DM75, \$26.40.

Theory of Slow Atomic Collisions. By E.E. NIKITIN and S. Ya. UMANSKII. Springer-Verlag. 1984. Pp.432. ISBN 3-540-12414-4/10-387-12414-4. DM 140.

Thin Film and Depth Profile Analysis. H. OECHSNER (ed.). Springer-Verlag. 1984. Pp.205. ISBN 3-540-13320-8/10-387-13320-8. DM72.

Time-Correlated Single Photon Counting. By DE-SMOND V. O'CONNOR and DAVID PHILLIPS. Academic. 1984. Pp.288. ISBN 0-12-524140-2. \$45, £31.

Treatise on Heavy-Ion Science, Vols 2 & 3. D. ALLAN BROMLEY (eds). Plenum. 1984. Vol. 2. Pp.734. ISBN 0-306-41572-0. Vol. 3. Pp.589. ISBN 0-306-41573-9. Np.

Chemistry

Advances in Heterocyclic Chemistry. ALAN R. KATRITZKY FRS (ed.). Academic. 1984. Pp.368. ISBN 0-12-020637-4. \$85, £65.

Advances in Organometallic Chemistry, Vol. 23. F.G.A. STONE and R. WEST (eds). Academic. 1984. Pp.319. ISBN 0-12-031123-2. \$65, £49.

Advances in Physical Organic Chemistry, Vol. 20. V. GOLD and D. BETHELL (eds). Academic. 1984. Pp.252. ISBN 0-12-033520-4. \$50, £35.

Analytical Measurement and Information: Advances in the Information Theoretic Approach to Chemical Analyses. By K. ECKSCHLAGER and V. ŠTĚPANEK. Wiley. 1985. Pp.140. ISBN 0-86380-021-1. £25.

The Central Science: Essays on the Uses of Chemistry. G.B. KAUFFMAN and H.H. SZMANT (eds). Texas Christian University Press. 1984. Pp.181. ISBN 0-912646-84-5. \$15.

Chemical Mössbauer Spectroscopy. R.H. HERBER (ed.). Plenum. 1984. Pp.378. ISBN 0-306-41885-1. Np.

Chemistry and Physics of Carbon. PETER A. THROWER (ed.). Dekker. 1984. Pp.360. ISBN 0-8247-7245-8. \$79.50.

Dictionary of Electrochemistry, 2nd Edn. By D.B. HIBBERT and A.M. JAMES. Macmillan, London. 1984. Pp.308. ISBN 0-333-34983-0. £20.

Encyclopedia of Electrochemistry of the Elements, Vol. 15. ALLEN J. BARD and HENNING LUND (eds). Dekker. 1984. Pp.324. ISBN 0-8247-2515-8. \$129.50, SwFr.324.

Food: The Chemistry of its Components. By T.P. COULTATE. Royal Society of Chemistry. 1984. Pp.197. Pbk ISBN 0-85186-483-X. Pbk £5.95.

Handbook of Chemical Equilibria in Analytical Chemistry. By S. KOTRLÝ and L. ŠŮCHA. Ellis Horwood. 1985. Pp.414. ISBN 0-85312-107-9. £45.

Infrared Spectrometry in Chemical Analysis: An Interactive Software Package. By D. KEALEY. Wiley. 1985. Np.

Metallo-Organic Chemistry. By ANTHONY J. PEARSON. Wiley. 1985. Pp.398. Pbk ISBN 0-471-90446-5. Pbk £9.95.

Mossbauer Spectroscopy Applied to Inorganic Chemistry, Vol. 1. GARY J. LONG (ed.). Plenum. 1984. Pp.667. ISBN 0-306-41647-6. Np.

Nuclear Analytical Chemistry. By DAG BRUNE, BENGT FORKMAN and BERTIL PERSSON. Charwell-Bratt, Old Orchard, Bickley Road, Bickley, Kent. 1984. Pp.557. ISBN 0-86238-0472-2. Np.

The Organic Chemistry of Drug Synthesis, Vol. 3. By D. LEDNICER and L.A. MITSCHER. Wiley. 1984. Pp.284. ISBN 0-471-09250-9. £37.95.

Organic Reaction Mechanisms, 1983. A.C. KNIPE and W.E. WATTS (eds). Wiley. 1985. Pp.589. ISBN 0-471-90503-8. £78.50.

Polymer Processing and Properties. GIANNI ASTARITA and LUIGI NICOLAIS (eds). Plenum. 1984. Pp.450. ISBN 0-306-41728-6. Np.

Practical Aspects of Gas Chromatography/Mass Spectrometry. By GORDON M. MESSAGE. Wiley. 1984. Pp.351. ISBN 0-471-06277-4. £69.35.

Statistics for Analytical Chemistry. By J.C. MILLER and J.N. MILLER. Ellis Horwood. 1984. Pp.202. ISBN 0-85312-662-3. £18.50.

A Symmetric Synthesis: Vol. 3 Stereodifferentiating Addition Reactions. JAMES D. MORRISON (ed.). Academic. 1984. Pp.578. ISBN 0-12-507703-3. \$69.50.

Techniques and Application of Thin Layer Chromatography. JOSEPH C. TOUCHSTONE and JOSEPH SHERMA (eds). Wiley. 1985. Pp.395. ISBN 0-471-88017-5. £88.65.

Techniques in Organic Reaction Kinetics. By PETR ZUMAN and RAMESH PATEL. Wiley. 1984. Pp.340. ISBN 0-471-03556-4. £57.25.

Computer Science

Computational Functional Analysis. By R.E. MOORE. Ellis Horwood. 1985. Pp.155. ISBN 0-85312-807-3. £15.

Computer Culture: The Scientific, Intellectual, and Social Impact of the Computer. HEINZ R. PAGELS (ed.). New York Academy of Sciences. 1984. Pp.288. Pbk ISBN 0-89766-245-8. Pbk \$66.

Distributed Computing Systems Programme. D A DUCE (ed.). Peter Peregrinus. 1984 Pp.305. ISBN 0-86341-023-5 £15, \$38.

Effective Fortran 77. By MICHAEL METCALF. Oxford University Press. 1985. Pp.231. Pbk ISBN 0-19-853709-3. Pbk £9.95.

Fundamentals of Human-Computer Interaction. ANDREW MONK (ed.). Academic. 1984 Pp.293. ISBN 0-12-504580-8. \$26.50, £18.50.

A Glossary of Computing Terms, 4th Edn. THE BRITISH COMPUTER SOCIETY. Cambridge University Press. 1984. Pp.58. Pbk ISBN 0-521-31778-9. Pbk £1.35.

Image Processing System Architectures. JOSEF KITTLER and MICHAEL J.B. DUFF (eds). Research Studies Press. 1985. Pp.166. ISBN 0-86380-023-8. £19.75.

The Microcomputer Users Handbook 1985. By DENNIS LONGLEY and MICHAEL SHAIN Macmillan, London. 1985. Pp.405. Pbk ISBN 0-333-36866-5. Pbk £4.99.

New Computer Architecture. J. TIBERGHEN (ed.). Academic. 1984. Pp.289. ISBN 0-12-690980-6. \$28.50, £19.50.

Silicon Shock: The Menace of the Computer Invasion. By GEOFF SIMONS. Basil Blackwell. 1985. Pp.191. ISBN 0-631-13835-8. £9.50.

Technology

Advances in Electrochemistry and Electrochemical Engineering, Vol. 13. By HEINZ GERISCHER and CHARLES W. TOBIAS. Wiley. 1984. Pp.360. ISBN 0-471-87881-2 £52.

Creep of Crystals: High-Temperature Deformation Processes in Metals, Ceramics and Minerals. By JEAN-PAUL POIRIER. Cambridge University Press. 1985. Pp.260. Pbk ISBN 0-521-27851-1. Pbk £10.95.

Electronic Synthesis of Speech. By R. LINGGARD. Cambridge University Press. 1985. Pp.149. ISBN 0-521-24469-2 £15, \$29.95.

Engineering Flow and Heat Exchange. By OCTAVE LEVENSPIEL. Plenum. 1984. Pp.366. ISBN 0-306-41599-2. \$34.50.

The Information Technology Revolution. TOM FORESTER (ed.). Basil Blackwell. 1985. Pp.674. Pbk ISBN 0-631-13438-7. Pbk £9.95.

Earth Sciences

Archaeological Geology. GEORGE RAPP Jr and JOHN A. GIFFORD (eds) Yale University Press. 1985. Pp.435. ISBN 0-300-03142-4 £35.

Coal Combustion and Gasification. By L. DOUGLAS SMOOT and PHILIP J. SMITH. Plenum. 1985. Pp.443. ISBN 0-306-41750-2. Np.

Coastline Changes: A Global Review. By ERIC C.F. BIRD. Wiley. 1985. Pp.219. ISBN 0-471-90646-8. £22.50.

Elements of Petroleum Geology. By RICHARD C SELLEY. W.H. Freeman. 1985. Pp.449. ISBN 0-7167-1630-5. \$44.95.

Feldspars and Feldspathoids: Structures, Properties and Occurrences. W. L. BROWN (ed.) Reidel. 1984. Pp.541. ISBN 90-277-1826-1. \$74, £49.50.

Hemispherical Projection Methods in Rock Mechanics. By S.D. PRIEST. George Allen & Unwin. 1985. Pp.124. Pbk ISBN 0-04-622007-0. Pbk £8.95.

Phanerozoic Earth History of Australia. By J.J. VEEVERS. Oxford University Press. 1985. Pp.418. ISBN 0-19-854459-6. £55.

Rocks and Minerals. By PAT BELL and DAVID WRIGHT. Hamlyn. 1985. Pp.192. Pbk ISBN 0-600-30556-2. Pbk £3.99.

Sedimentation on the Continental Shelf with Special Reference to the East China Sea. ACTA OCEANOLOGICA SINICA (ed.). Springer-Verlag. 1983. Pp.952. ISBN 3-540-12648-1. DM 475

Environmental Sciences

Air Pollution Modelling and its Applications, Vol. 4. NATO Challenges of Modern Society, Vol. 7. C. DE WISPELAERE (ed.). Plenum. 1985. Pp.818. ISBN 0-306-41908-4. Np.

Causes and Effects of Changes in Stratospheric Ozone: Update 1983. COMMITTEE ON CAUSES AND EFFECTS OF CHANGES IN STRATOSPHERIC OZONE. National Academy. 1984. Pp.254. ISBN 0-309-03443-4. Np.

Environmental Evaluation: Perception and Public Policy. By ERVIN H. ZUBE. Cambridge University Press. 1985. Pp.148. ISBN 0-521-31972-2. Pbk £5.95.

Environmental Science: A Framework for Decision Making. By DANIEL D. CHIRAS. Benjamin Cummings. 1985. Pp.655. ISBN 0-8053-2255-8. \$33.95.

Social and Economic Aspects of Radioactive Waste Disposal: Considerations for Institutional Management. PANEL ON SOCIAL AND ECONOMIC ASPECTS OF RADIOACTIVE WASTE MANAGEMENT. National Academy. 1984. Pp.175. ISBN 0-309-03444-2. Np.

Technical Report Series, Vol. 718: Environmental Pollution Control in Relation to Development. WORLD HEALTH ORGANISATION EXPERT COMMITTEE. World Health Organisation. 1985. Pp.63. ISBN 0-92-4-1207187-3. SwFr.6.

Biological Sciences

Acquired Immunodeficiency Syndrome (AIDS): Advances in Host Defense Mechanisms, Vol. 5. JOHN I. GALLING and ANTHONY S. FAUCI (eds). Raven. 1985. Pp.178. ISBN 0-88167-077-4. \$42.

Adaptation to Altitude-Hypoxia in Vertebrates: Zoophysiology, Vol. 16. By PIERRE BOUVEROT. Springer-Verlag. 1985. Pp.176. ISBN 3-540-13602-9/0-387-13602-9. DM94.

Advances in Anatomy Embryology and Cell Biology, Vol. 86. By JEFFREY A. WINER. Springer-Verlag. 1984. Pp.97. ISBN 3-540-13524-6. DM58.

Advances in Anatomy Embryology and Cell Biology, Vol. 92. Angiographic Anatomy of the Anterior Inferior Cerebellar Artery. By JAN J. HEIMANS, JAAP VALK and ANTHONY H.M. LOHMAN. Springer-Verlag. 1985. Pp.91. ISBN 3-540-13768-8/0-387-13768-8. DM58.

Advances in Cardiology, Vol. 32. Assessment of Ventricular Function. D.H. SPODICK (ed.). Karger. 1985. Pp.153. ISBN 3-8055-3993-2. SwFr126, DM151, \$53.75.

Advances in Human Genetics. H. HARRIS and K. HIRSCHHORN (eds). Plenum. 1985. Pp.399. ISBN 0-306-41752-9. Np.

Advances in Microbial Ecology. K.C. MARSHALL (ed.). Plenum. 1985. Pp.307. ISBN 0-306-41877-0. Np.

Advances in Myocardiology 6. N.S. DHALLA and D.J. HEARSE (eds). Plenum. 1985. Pp.669. ISBN 0-306-41759-6. Np.

Algal Cell Biology. By H.D. KUMAR. East-West Press. 1985. Pp.201. Pbk Rs 41.

Animal Behaviour. By DAVID MCFARLAND. Pitman. 1985. Pp.576. ISBN 9-780273-021032. £11.95.

Animal Intelligence. L. WEISKRANTZ (ed.). Oxford University Press. 1985. Pp.223. ISBN 0-19-852124-3. £32.50.

Auditory Development in Infancy. SANDRA E. TREHUB and BRUCE SCHNEIDER (eds). Plenum. 1985. Pp.243. ISBN 0-306-41757-X. Np.

Autonomic Functions in Human Physiology. By G. THEWS and P. VAUPEL. Springer-Verlag. 1985. Pp.384. ISBN 3-540-13217-1/0-387-13217-1. DM39.80, \$14.

Structural and Resonance Techniques in Biological Research. DENIS L. ROUSSEAU (ed.). Academic. 1984. Pp.476. ISBN 0-12-599320-X. \$69, £52.

Surgical Management of the Burn Wound. By DAVID M. HEIMBACK and LOREN H. ENGRAV. Raven. 1984. Pp.161. ISBN 0-89004-914-9. \$93.50.

Synthetic Pyrethroids and Other Pesticides. G. ZWEIG and J. SHERMA (eds). Academic. 1984. Pp.312. ISBN 0-12-784313-2. \$65, £49.

Transnasal Systemic Medications: Fundamentals, Developmental Concepts and Biomedical Assessments. YIE W. CHIEN (ed.) Elsevier. 1985. Pp.226. ISBN 0-444-42460-1. Dfl145, \$53.75.

Two-Dimensional Gel Electrophoresis of Proteins: Methods and Applications. JULIO E. CELIS and RODRIGO BRAVO (eds). Academic. 1984. Pp.487. ISBN 0-12-164720-X. \$69.50.

Understanding Dental Caries: Etiology and Mechanisms. By GORDON NIKIFORUK. Karger. 1985. Pp.306. ISBN 3-8055-3864-2. DM69, \$34.75.

Wildlife Pest Control Around Gardens and Homes. By TERRELL P. SALMON and ROBERT E. LICKLITER. University of California Division of Agriculture and Natural Resources. 1984. Pp.90. Pbk ISBN 0-931876-66-4. Np.

Archaeology

Excavations at Grimes Graves Norfolk 1972-1976. By JULIET CLUTTON-BROCK. British Museum Publications. 1985. Pp.46. Pbk ISBN 0-7141-1374-3. Pbk £10.

The Greek Trireme of the 5th Century B.C. JOHN COATES and SEAN McGRAIL (eds). National Maritime Museum, Greenwich. 1985. Pp.140. Pbk ISBN 0-905555-95-3. Pbk £8.

Paleopathology at the Origins of Agriculture. MARK NATHAN COHEN and GEORGE J. ARMELAGOS (eds). Academic. 1984. Pp.615. ISBN 0-12-179080-0. \$59, £41.50.

The Palynology of Archaeological Sites. By GEOFFREY W. DIMBLEBY. Academic. 1985. Pp.176. ISBN 0-12-216480-6. \$45, £46.

General

Handbook of Discourse Analysis, Vol.1. Disciplines of Discourse. TEUN A. VAN DIJK (ed.). Academic. 1985. Pp.302. ISBN 0-12-712001-7. \$59.50, £45.50.

High Altitude Deterioration. J. RIVOLIER et al. (eds). Karger. 1985. Pp.228. ISBN 3-8055-3972-X. DM 174, \$61.75.

Ideas, Qualities and Corpuscles: Locke and Boyle on the External World. By PETER ALEXANDER. Cambridge University Press. 1985. Pp.336. ISBN 0-521-26707-2. £27.50.

Image Understanding 1984. SHIMON and WHITMAN RICHARDS (eds). Ablex Publishing, 355 Chestnut Street, Norwood, New Jersey. 1985. Pp.268. ISBN 0-89391-254-9. \$35.

Modern Trends in Hypnosis. DAVID WAXMAN et al. (eds). Plenum. 1985. Pp.429. ISBN 0-306-41905-X. Np.

Multivariable Control: New Concepts and Tools. SPYROS G. TZAFESTAS (ed.). Reidel. 1984. Pp.502. ISBN 90-277-1829-6. Dfl 1230, \$49.50, £33.25.

Nuclear Fact Book, 2nd Edn. A.M. PLATT, J.V. ROBINSON and O.F. HILL (eds). Harwood Academic. 1985. Pp.176. ISBN 3-7186-0273-3. \$33.

On the Frontier: Flight Research at Dryden, 1946-1981. By RICHARD P. HALLION. NASA. 1984. Pp.385. Np.

Proceedings of the Royal Institution of Great Britain, Vol. 56. NINA HALL and IVOR WILLIAMS (eds). Science Reviews. 1984. Pp.288. ISBN 0-905927-81-8. Np.

Public Health Papers, Vol. 81: Community Response to Alcohol-related Problems: Review of an International Study. By E.B. RITSON. World Health Organisation. 1985. Pp.58. ISBN 92-4-130081-7. Np.

The Regional Economic Impact of Technological Change. A.T. THWAITES and R.P. OAKLEY (eds). Frances Pinter. 1985. Pp.249. ISBN 0-86187-373-4. £17.50.

Research: How to Plan, Speak and Write About it. CLIFFORD HAWKINS and MARCO SORGI (eds). Springer-Verlag. 1985. Pp.184. ISBN 0-387-13992-3/ ISBN 3-540-13992-3. DM 32.

Revelations: Glimpses of Reality. RONALD S. LELLO (ed.). Shephard-Walwyn. 1985. Pp.136. ISBN 0-85683-079-8. £8.50.

Safeguarding the Atom: A Critical Appraisal. JOZEF GOLDBLAT (ed.). SIPRI. 1985. Pp.243. ISBN 0-85066-306-7. Np.

Science and Technology Policies in Finland and Hungary: A Comparative Study. K.O. DONNER and L. PAL (eds). Akadémiai Kiadó, Budapest. 1985. Pp.371. ISBN 963-05-3977-2. £19.75.

United States Arctic Interests: The 1980s and 1990s. WILLIAM E. WESTERMEYER and KURT M. SHUSTERICH (eds). Springer-Verlag. 1984. Pp.369. ISBN 0-387-96009-0. DM 114.

NOTTINGHAM UNIVERSITY

DEPARTMENT OF BIOCHEMISTRY

POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for a post-doctoral position to isolate and characterise gene sequences for proteins associated with specific brain diseases. The work will establish the origin and regulation of the proteins concerned, and will prove useful in the molecular diagnosis of the diseases.

This grade 1A Wellcome Trust-supported position, tenable for three years has a starting salary of 7,520 pounds (under review) including USS benefits.

Applicants with suitable experience in recombinant DNA technology should send a curriculum vitae and the names of two referees to Dr Robert E. Glass and Dr Michael A. Billett, Department of Biochemistry, Medical School, Queen's Medical Centre, Nottingham NG7 2UH (telephone 0602-700111) from whom further information may be obtained. (7193)A

THE LONDON HOSPITAL MEDICAL COLLEGE (University of London)

MLSO IN HISTOPATHOLOGY

Applications for a MLSO in Histopathology are required for the Experimental Pathology Department of the London Hospital Medical College. HNC/TEC pass or an appropriate science degree required, and facilities are available for taking further qualifications. The job entails the assistance with experiments, radioactive isotopes, upkeep and development of computer programs for record keeping, audio visual aids and image analysis. Post vacant with effect from 1st October 1985.

Salary range MLSO £6,488 to £8,789 inclusive of London Weighting (under review). Application forms are available from the Assistant Secretary, the London Hospital Medical College, Turner Street, London E1 2AD (01-377-8800 ext 12), and should be returned within 21 days of this advertisement. (7194)A

INSTITUTE OF DERMATOLOGY UNIVERSITY OF LONDON WELLCOME SKIN PHARMACOLOGY LABORATORIES

Postdoctoral research associate (pharmacology) required for MRC Programme Grant-supported research on molecular mechanisms of skin inflammation. The current emphasis of the work is on lipoxigenase products and studies are in progress in human subjects and using cultured keratinocytes. The successful candidate, who will be responsible to the Professor of Dermatology, should have substantial post-doctoral experience in pharmacological aspects of inflammation and will be considered for an honorary lectureship in the Institute. Salary scale: £7,520-£12,150 plus London Weighting.

Applications, with the names of two referees, to: Professor M.W. Greaves, Wellcome Skin Pharmacology Laboratories, Institute of Dermatology, Homerton Grove, London E9 6BX. (7192)

ROYAL HOLLOWAY AND BEDFORD COLLEGES

Egham Hill, Egham,
Surrey TW20 0EX

DEPARTMENT OF BIOCHEMISTRY RESEARCH ASSISTANT

Required for 3 years from 1st October 1985 to work with Dr. J. R. Bowyer on the electron acceptors of chloroplast Photosystem II. Candidates should have a least a 2(i) Honours Degree in Physics or related science with a knowledge of electronics and optical instrumentation, and a desire to apply this knowledge to a biological system. The project involves the construction of a very sensitive rapidly-responding spectrophotometer and its application to measure absorption changes associated with photosynthetic electron transport. Candidates may register for a higher degree. Salary will be on the 1B range for Research Staff on a scale £7,833-£8,753 inclusive of London allowance.

Applications with cv and the names and addresses of 2 referees should be sent to Mrs D. J. Odds, Personnel Officer. (7200)A

OFFICE OF INTERNATIONAL AFFAIRS OFFICE OF THE DIRECTOR NATIONAL CANCER INSTITUTE PUBLIC HEALTH SERVICE DEPARTMENT OF HEALTH AND HUMAN SERVICES

ASSOCIATE DIRECTOR FOR INTERNATIONAL AFFAIRS

The National Cancer Institute (NCI) interacts with scientists throughout the world to promote the advancement of cancer research, treatment and prevention. These activities result in bilateral agreements with other countries for cooperative research, the collection and dissemination of scientific knowledge worldwide, and the increased use of computer technology to improve these information transfers. The Office of International Affairs (OIA) is responsible for the planning, coordination, and management of these efforts within the NCI. OIA has an annual operating budget of approximately \$9 million.

This is a Civil Service position in the Senior Executive Service (SES) with a salary range from \$61,296 to \$68,700 per annum. Candidates may be eligible for Physicians' Comparability Allowance up to \$10,000 per year. (Alternately, candidates may be eligible for appointment in the Commissioned Corps of the U.S. Public Health Service.) The individual selected, if not presently in SES, must serve a one year probationary period.

Candidates must meet established mandatory professional/technical and managerial/executive requirements. Candidates will be further evaluated on the extent they exceed the minimum requirements and on additional factors including scientific reputation/peer recognition, training and education, and honors and awards. A copy of the requirements may be obtained by contacting **Ms. Valerie Barbour, Personnel Management Branch, NCI, (301) 496-6864.**

Applications (Personal Qualifications Statement SF-171) are to be sent to the above individual at: **The National Cancer Institute, Building 31, Room 3A-23, 9000 Rockville Pike, Bethesda, Maryland 20205.** A current curriculum vitae and bibliography must accompany all applications. Applications from women and minority group members are especially solicited.

*The National Institutes of Health is an
EQUAL OPPORTUNITY EMPLOYER.*

Experimental Solid State Physicists

Vacancies exist for solid state physicists to work in the neutron scattering experimental programme at the Rutherford Appleton Laboratory's Spallation Neutron Source. The SNS is an intense, pulsed source which has recently become operational and which is of world significance to future research in the fields of physics, chemistry, biology and materials science.

The appointees would be expected to advance the use of neutron inelastic scattering in the study of condensed matter and the duties would involve developing new neutron spectrometers as well as providing experimental support to University groups which use the SNS facility. Candidates are also expected to be capable of making significant contributions of their own to the future SNS scientific programme. Previous experience in neutron, x-ray or electron scattering techniques is desirable but not essential. Applicants should however have demonstrated their research potential and ideally have some experience of instrumentation development or computing.

The appointments will be made in the Higher Scientific Officer grade salary range £7788-£10541 per annum.

Candidates should have a degree or equivalent in a scientific subject, plus at least 2 years post graduate research experience for applicants with 1st or 2nd class honours degrees or their equivalent. Other applicants are required to have at least 5 years of appropriate scientific experience after qualifying.

The Rutherford Appleton Laboratory is a friendly community with its own restaurant and sports facilities. Our transport covers towns and villages in the area. Excellent working conditions and generous holidays apply. This is a pensionable appointment.

Contact Recruitment Office, Personnel Group, Science and Engineering Research Council, Rutherford Appleton Laboratory, Chilton, Didcot, Oxon OX11 0QX, Tel: (0235) 445435, quoting reference VN 364.

Closing date: 16th August 1985

pathologist drug safety evaluation

An opportunity exists in the Pathology Group at SEARLE RESEARCH and DEVELOPMENT Center located in the South of France.

The candidate should have a D.V.M., M.D. or Ph.D degree in Pathology and at least five years experience (preferably in the pharmaceutical industry) in veterinary pathology.

The successful candidate will act as pathologist (slide reading and interpretation) on preclinical safety studies and will be involved in pathology research programs.

SEARLE R & D offers excellent laboratory facilities; competitive salaries, benefits and paid relocation. The Center is located in a particularly attractive part of France between Nice and Cannes, and is a part of G.D. SEARLE and Co., an international pharmaceutical company.

Applications with a full C.V. including current salary should be addressed to :

Mr G. du Parc, Personnel Manager,
SEARLE Recherche et Développement
Sophia Antipolis - B P. 23
06561 VALBONNE Cedex, FRANCE. (Ref. N.7)

(W2049)A

THE AUSTRALIAN NATIONAL UNIVERSITY RESEARCH SCHOOL OF EARTH SCIENCES POSTDOCTORAL FELLOW/ RESEARCH FELLOW/ SENIOR RESEARCH FELLOW IN ORE-GENESIS STUDIES

Applications are invited from suitably qualified women and men for appointment as Postdoctoral Fellow Grade 1, Research Fellow or Senior Research Fellow in ore-genesis studies in the Research School of Earth Sciences. The appointee will work with Dr I. H. Campbell, Senior Fellow, in developing research in this field. The School wishes to make the appointment at the Research Fellow level, but will be prepared to consider applications at the level PDF or SRF. The appointment initially will be in the Geophysical Fluid Dynamics Group of the School, but it is possible that the ore-genesis work will be organized as a separate research group as it becomes well established.

The overall brief for ore-genesis studies is to carry out fundamental research, identify fundamental problems which are of interest to other groups within the School, and coordinate the School's total programme in ore-genesis studies. Collaboration with relevant organizations outside the School, including Australian mining companies, will be important.

Persons with suitable backgrounds in geology and geochemistry are encouraged to apply.

Closing date: 13 September 1985.
Ref: ES27.6.1.

Conditions of appointment: Salary will be in accordance with qualifications and experience within the range: Postdoctoral Fellow Grade 1 \$A22,614-\$25,905 p.a.; Research Fellow \$A26,236-\$34,467 p.a.; Senior Research Fellow \$A36,649-\$43,715 p.a.; current exchange rate \$A1=UK 51p.

Appointment, unless otherwise stated, will be: Senior Research Fellow/Research Fellow normally up to three years with the possibility of extension to maximum of five years; Postdoctoral Fellow normally two years, with the possibility of extension to maximum of three years.

Grants are provided towards travel and removal. Assistance towards housing is given to an appointee from outside Canberra. Eligible appointees will be required to join the Superannuation Scheme for Australian Universities. Maternity leave is available. The University reserves the right not to make an appointment or to make an appointment by invitation at any time.

Applications should be submitted to the Acting Registrar, Australian National University, GPO Box 4, Canberra, ACT 2601, Australia. Applicants should quote the reference number when submitting applications and when requesting further particulars, which are also available from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

The University is an Equal Opportunity Employer. (W2050)A

ETH ZÜRICH

The Swiss Federal Institute of Technology in Zurich invites applications for a faculty position in Food and Agricultural Chemistry.

Duties of the new professor include the teaching of food chemistry and food biochemistry (including laboratories) for food science students and, in cooperation with other professors, organic chemistry for students in agriculture and forestry.

The successful candidate will have proven ability to conduct research in the chemistry, biochemistry and analysis of foodstuffs and talent for teaching at all university levels.

Applications with c.v. and list of publications should be submitted before September 30, 1985, to the President of ETHZ, Prof. H. Ursprung, ETH-Zentrum, 8092 Zurich, Switzerland. (W2046)A

Senior Chemist for Peptide Synthesis

To strengthen our developing medicinal chemistry group, we are looking to appoint a chemist who will play a significant role in the synthesis of novel peptides.

We are Merck Sharp and Dohme Research Laboratories, Neuroscience Research Centre, newly established on a 30 acre site near Harlow, Essex. Initially focussing on the study of inhibitory chemical messengers in the brain and exploration of the functional role of neuropeptides, we shall be one of the world's largest centres dedicated to neuroscience research.

Applications are invited from candidates who are Ph.D. Chemists with a minimum of two years postdoctoral experience and have specialised in peptide synthesis and are seeking a permanent post in medicinal chemistry research. Alternatively, consideration will be given to outstanding Ph.D.'s who have specialised in peptide synthesis for a postdoctoral fellowship of one to two years duration. Applications enclosing a full C.V. to:

Mr. P. A. Harley, Personnel Manager, Merck Sharp and Dohme Research Laboratories, Neuroscience Research Centre, Terlings Park, Eastwick Road, Harlow, Essex CM20 2QR.

BIOCHEMISTRY

Microgenics is a biotechnology company which has developed an advanced and proprietary diagnostic test system based on protein engineering by recombinant DNA techniques. New positions are available for exceptional research scientists.

IMMUNOCHEMISTS, PhD. Candidates will supervise product development of CEDIA homogeneous enzyme immunoassay. A PhD in immunology or chemistry and prior industrial product development experience required. Candidates will be familiar with validation of diagnostic assays, generation of GLP/GMP protocols, and submission of FDA documentation.

CHEMISTS/BIOLOGISTS, BA/BS/MS. Candidates will be familiar with the performance and documentation of an EIA/ELISA-510(k) validation. Responsibilities will include development of commercial immunoassays and applicable FDA documentation. Supervisory experience preferred.

MOLECULAR BIOLOGISTS, PhD. Candidates will protein engineer hybrid and tribrid polypeptides at the recombinant DNA level for commercial immunoassays within eukaryotic and prokaryotic expression vectors.

CHEMISTS/BIOLOGISTS, BA/BS/MS. Candidates will function in protein chemistry with a practical knowledge of liquid chromatography, SDS-PAGE, Western-Blots and enzyme-immunoassays.

Microgenics offers a scientific challenge and equity participation with competitive salaries and fringe benefits. For immediate consideration, forward your resume in strict confidence to:

CSIRO

AUSTRALIA

RESEARCH IN RESOURCE INFORMATION TECHNOLOGY

\$A26,001 — \$A38,243

DIVISION OF WATER AND LAND RESOURCES

CANBERRA ACT

CSIRO conducts scientific and technological research in laboratories located throughout Australia and employs about 7,500 staff, of whom some 2,900 are professional scientists. The Organization's research activities are grouped into five Institutes: Animal and Food Sciences, Biological Resources, Energy and Earth Resources, Industrial Technology and Physical Sciences. The CSIRO Division of Water and Land Resources is a member of the Institute of Biological Resources.

GENERAL: The Division of Water and Land Resources conducts research into methods for improved inventory, evaluation planning and management of the nation's water and land resources. The development of computer based methods for acquiring, storing, retrieving and analysing resource data for re-establishment of national, State and regional geographic information systems forms an important aspects of this research.

DUTIES. Collaborate in the research of the Catchment Hydrology Program to develop methods for the representation and analysis of spatially distributed data and the interpolation of spatial and temporal data through the definition of mathematical models for terrain and climate analysis. This program has research teams addressing questions in the fields of land and water resource management and in applications to catchment hydrology.

QUALIFICATIONS: A PhD degree or equivalent qualifications in mathematics and statistics and qualifications and/or experience in numerical analysis and computer programming, preferably including experience in the design and development of geographic information systems and in digital elevation modelling. Experience with processing and analysing cartographic data is desirable.

TENURE: Indefinite with Australian Government superannuation benefits available.

APPLICATIONS: Stating relevant personal particulars, including details of qualifications and experience, the names of at least two professional referees and quoting reference No A3132, should be directed to:

The Chief
CSIRO Division of Water and Land Resources
GPO Box 1666
CANBERRA ACT 2601
by 4 weeks from publication

CSIRO IS AN EQUAL OPPORTUNITY EMPLOYER (W2058)A

KEY CENTRE IN STATISTICAL SCIENCES LECTURESHIPS (LIMITED TENURE)

Applications are invited for several positions in the recently created Commonwealth Tertiary Education Commission (CTEC) Key Centre for Teaching and Research in the Statistical Sciences. The Key Centre involves the Departments of Statistics of La Trobe University and The University of Melbourne, the Statistics Section of the Department of Mathematics of Monash University and the Statistics and Operations Research Group of the Department of Mathematics, Royal Melbourne Institute of Technology. It is intended to make up to four appointments, initially for periods of up to three years. Some of the positions may involve statistical consulting as a major component of the duties. Appointees will be expected to have a strong background in some area of mathematical statistics or probability theory and to be active in research.

The positions are available immediately. Salary will be in the range \$A26,230–\$A34,467 per annum.

Further information concerning the positions for the Statistical Sciences Key Centre may be obtained from: The Director, Professor C. C. Heyde, Department of Statistics, The University of Melbourne, Parkville, Victoria 3052, Australia, telephone (03) 344 6609 or from the Heads of any of the constituent departments.

Applications, in duplicate, including the names and addresses of at least three referees should be addressed to: The Staff Officer, The University of Melbourne, at the above address, quoting position number 619 A575.

Applications close on 23rd September, 1985. Applicants should state whether they have a preference for appointment at one or other of the constituent institutions. (W2047)A

THE AUSTRALIAN NATIONAL UNIVERSITY

Applications are invited from suitably qualified men and women for appointment to the following positions:

John Curtin School of Medical Research

DEPARTMENT OF MEDICINE AND CLINICAL SCIENCE

POSTDOCTORAL FELLOW GRADE I (NBP)

The appointee will work with Dr. R. Stephens on the function and regulation of plasminogen activating enzymes in human cancer. Applicants should have a PhD degree, background in enzymology, cell biology, or tumour biology with biochemical perspective, and preferably experience in the generation and biochemical applications of monoclonal antibodies. Appointment will be for one year initially, with the possibility of extension for several months to a total period of about eighteen months. The position is funded through a National Biotechnology Program Research Grant Enquiries to Dr R. Stephens in the University (062) 84 2890. Background information may be obtained from the Acting Registrar.

Closing date: 22 August 1985. Ref. JC 6.6.1.

Faculty of Science

DEPARTMENT OF BIOCHEMISTRY

TEMPORARY LECTURER IN BIOCHEMISTRY (MICROBIOLOGY)

The successful applicant will be required to make a substantial contribution to the teaching of General Microbiology in a two semester course for second year science students. The research interests of the appointee should be compatible with one or more of the areas of microbiology established in the Department: molecular biology of antibiotic resistance and virulence in bacteria; alphavirus and flavivirus structure, replication and pathogenesis; cyanobacterial metabolism. The appointment is for 3 years from 1 January 1986 to 31 December 1988. Enquiries to Professor J. F. Williams in the University (062) 492284 or Dr P. R. Stewart (062) 492226.

Prospective applicants should write for further particulars to the Acting Registrar of the University.

Closing date: 16 August 1985. Ref: FS 4.7.1.

Conditions of appointment: Salary will be in accordance with qualifications and experience within the range: Postdoctoral Fellow Grade 1 \$A22,614–\$25,905 p.a.; Temporary Lecturer \$A26,236–\$34,467 p.a.; current exchange rate \$A1=UK50p.

Grants are provided towards travel and removal, though special conditions may apply to persons appointed to externally funded positions. Assistance towards housing is given to an appointee from outside Canberra. Eligible appointees will be required to join the Superannuation Scheme for Australian Universities. Maternity leave is available. The University reserves the right not to make an appointment or to make an appointment by invitation at any time. Applicants should quote the advertisement reference when submitting applications, and when requesting further particulars, which are also available from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Applications should be submitted to the Acting Registrar, Australian National University, GPO Box 4, Canberra, ACT 2601, Australia.

THE UNIVERSITY IS AN EQUAL OPPORTUNITY EMPLOYER. (W2055)A

TRENT POLYTECHNIC POSTDOCTORAL RESEARCH FELLOWS (TWO POSTS)

(Commencing Salary £8,010 — pay award pending)

DEPARTMENT OF LIFE SCIENCES

HERBICIDES

Required to join the Herbicide Research Group for a project entitled "The Physiology and Biochemistry of Herbicide Action". Applicants should have expertise in Plant Physiology/Biochemistry and be skilled in a range of biomedical techniques. Previous experience with herbicides and macromolecular synthesis would be advantageous but not essential. Ref NAB/LS/1.

BIOCHEMICAL PHARMACOLOGY

Required to join a small group investigating the importance of Ca^{2+} -mediated events to membrane interactions involved in stimulus secretion coupling in pancreatic islets and other tissues. Candidates should have a sound background in cell biochemistry with expertise in related techniques. Ref NAB/LS/2.

Please quote the reference number of the post for which you wish to apply. Further details and forms of application are available from the Staff Officer, Trent Polytechnic, Burton Street, Nottingham NG1 4BU. Closing date: 9th August 1985. (7208)A

Challenging Opportunities in Diagnostics R & D

Beckenham, Kent

The Wellcome Foundation Ltd. is an international group of chemical and pharmaceutical companies, with headquarters in the UK, and turnover close to £800m. Wellcome Diagnostics is an expanding commercial division of the group concerned with the design, development and manufacture of

diagnostic reagents.

At Wellcome's main research centre at Beckenham, we have opportunities for experienced scientists to take up key positions in the multi-disciplinary Department of Diagnostics R & D, a constituent of the Biomedical Research Division.

Section Leader (Virology) Starting salary up to £20,000

Leading a team of 11 post-doctoral scientists and graduate level technicians, you will contribute to the formulation and implementation of our research and development effort in this area.

You will possess at least 10 years' post-doctoral research experience with an acknowledged record of achievement in a virological field and preferably some knowledge of diagnostics. A flair for team leadership, the ability to respond dynamically to pressure and to interact effectively and authoritatively with commercial departments are essential attributes. Ref. WRL/351.

Research Virologist In excess of £12,000

To bring a successful background of virological research to our viral diagnostics team and the ability to make a major contribution to novel work in this area. Your post-doctoral experience of at least 5 years will have demonstrated a flair for creativity and innovation.

An ability to interact with both scientists and commercial personnel is essential. Ref. WRL/352.

Development Scientist (Bacteriology) In excess of £12,000

To lead a group of experienced bacteriologists involved in the development stages of the R & D process.

You will possess at least 5 years' post-doctoral bacteriology experience in an academic, industrial or hospital environment. Your function will include the provision of assistance to the Development Manager in the co-ordination and administration of development projects. Organisational skills and a flair for motivating scientific teams are essential, together with an ability to interact with research, production and marketing personnel. An aptitude for producing written communications is an essential requisite for this position. Ref. WRL/353.

Our starting salaries will reflect the importance of these positions and will be dependent on experience. Excellent benefits package includes five weeks' holiday, pension fund, sick pay scheme, subsidised restaurant and assistance with relocation expenses where appropriate.

Please write with full details, quoting the appropriate reference, to Dr. H. D. Avshu, Personnel Officer, The Wellcome Research Laboratories, Langley Court, Beckenham, Kent BR3 3BS.

(7226)A

Wellcome

BIOLOGIST

The Department of Molecular, Cellular, and Developmental Biology of the University of Colorado is seeking an Assistant Professor. The candidate's research specialty may be in any area where molecular techniques are now predominant: Plant biology, virology, developmental genetics, mechanisms of prokaryotic and eukaryotic gene expression, and molecular pathogenesis are some suitable areas. Evidence of ability to initiate and sustain an outstanding research program will be paramount, and the candidate should have postdoctoral experience. This tenure-track position will be available in September, 1986, though applications for the year following are encouraged.

Please send curriculum vitae, reprints, the names of three professional references, and other relevant material to: Search Committee, MCDB, Campus Box 347, University of Colorado, Boulder, CO 80309.

Deadline for application is October 15, 1985. Applications from women and members of minorities are sought and will be welcomed. (NW69)A

POSTDOCTORAL POSITION CARDIAC/SMOOTH MUSCLE ELECTROPHYSIOLOGY

Unique industrial and academic postdoctoral position to study ionic channel properties of isolated cardiac and smooth muscle cells and modulation by pharmacological and biochemical agents. Project will involve use of single cardiac and vascular smooth muscle cells for voltage clamp and internal perfusion as well as patch clamp techniques. Candidates should have a strong background in electrophysiology. For the first year, the successful candidate will work with: **Dr. J.R. Hume, Department of Pharmacology and Toxicology, Michigan State University, East Lansing, Mich. 48824;** the second year will be spent with: **Dr. Kai S. Lee at the Upjohn Company in Kalamazoo, Mich. 49001.**

Salary commensurate with experience and qualifications.

Send curriculum vitae and three letters of reference to: Dr. Hume (above address). Deadline for receipt of applications is September 1, 1985. (NW56)A

CSIRO

AUSTRALIA

REGIONAL

OFFICER-IN-CHARGE

\$A39,692 — \$A52,232

DIVISION OF SOILS

ADELAIDE LABORATORY

URRBRAE SA

CSIRO conducts scientific and technological research in laboratories located throughout Australia and employs about 7,500 staff, of whom some 2,900 are professional scientists. The Organization's research activities are grouped into five Institutes: Animal and Food Sciences, Biological Resources, Energy and Earth Resources, Industrial Technology and Physical Sciences. The CSIRO Division of Soils is a member of the Institute of Biological Resources.

GENERAL: CSIRO Division of Soils studies the biology, chemistry, mineralogy and physics of soils, as well as the integrative disciplines of pedology and geomorphology. It also seeks to apply the principles of soil science in agriculture, forestry, hydrology, engineering and conservation. The Division has laboratories in Adelaide, Brisbane, Canberra and Townsville with scientific management based on five research coordinators responsible to the Chief for the scientific direction and quality of research in the five major sub-disciplines of the subject.

The Division seeks an Officer-in-Charge of its Adelaide laboratories. These laboratories represent about half the complement of the Division, with a total staff of approximately 100, half of whom are professional scientists. **RESPONSIBILITIES:** The appointee, who will be an outstanding scientist, will provide scientific and administrative leadership for this laboratory, and will be directly responsible to the Chief of the Division, who is located in Canberra. He or she will be encouraged to rationally delegate responsibility, in order to maintain a strong personal commitment to scientific study and research. As principal representative of the Division in South Australia, the Officer-in-Charge will be expected to interact with State instrumentalities, the universities and other agencies with interests common to the Division of Soils.

The appointee will also be responsible to the Chief of Division of financial resource allocation in Adelaide. In the scientific stream this allocation will be effected in consultation with the five Research Coordinators; in the administrative area the site will be managed through professional administrative staff headed by a Divisional Administrative Officer responsible to the Officer-in-Charge.

QUALIFICATIONS: A PhD degree or equivalent qualifications plus an outstanding record of personal research achievement and leadership in a relevant field of soil science is essential. Broad management experience would be an advantage.

TENURE: Indefinite with Australian Government superannuation benefits available.

The appointment as Officer-in-Charge will be for an initial term of four years, with the possibility of a further term if mutually desired.

NOTE: Consideration will be given to appointment of an outstanding applicant at a higher salary.

A Higher Duties Allowance may be appropriate for the duties associated with the Officer-in-Charge position.

The Chief of the Division of Soils, Dr D E Smiles (Telephone Canberra 062 464911), would be pleased to discuss the position in more detail with potential applicants.

APPLICATIONS: Stating relevant personal particulars, including details of qualifications and experience, the names of at least two professional referees and quoting reference No A5254, should be directed to:

The Chief
CSIRO Division of Soils
GPO Box 639

An Equal Opportunity Employer.

(NW68)A

Post Doctoral Positions (2)

Available in September and December, 1985 to study the molecular basis of action of insulin and related growth factors that activate tyrosine kinases/receptors.

Individuals are sought with training in biochemistry or cell biology with interests in either protein chemistry or the cell biology of intracellular vesicular traffic.

Please send curriculum vitae and the names of three references to: Dr. Paul F. Pilch, Department of Biochemistry, Boston University School of Medicine, 80 East Concord St., Boston, MA 02118. EOE/m/f. (NW59)A

Cytologists

...make a career move into applications marketing
salary negotiable to £14,000 plus car

This is an excellent opportunity for young cytologists involved in particular in screening for cancer of the cervix through the cervical smear technique (use of PAP stain etc.), to make their first move into marketing with an established bio-medical instrumentation company. As a leader in the field, innovation and outstanding design has become a hallmark.

To launch a new image analysis product an Applications Specialist is required to investigate user requirements in the cytology market. Key responsibilities include advising on strategic aspects of marketing, the development of product documentation packages, carrying out machine demonstrations on customer sites, training

end-users and prospecting for machine sales.

Candidates, aged ideally 25 to 35 will have a sound theoretical and practical knowledge of cytology as practiced in the UK and European medical establishments. They will be qualified to HNC/Degree level in Biology, Genetics, Botany, or Zoology. Most importantly, they must feel comfortable with the man-machine interface and should be able to demonstrate clear interpersonal and persuasive skills

Salary is negotiable to £14,000 plus fully expensed company car. The location is North Cheshire.

Applicants should write with full c.v. quoting ref. AR/073 to: March Personnel Services, 33 King Street, Manchester M2 6AA.

Cell biology-physiology-biochemistry laboratory studying isolated cardiac membrane channel proteins seeks

IMMUNOLOGIST OR PROTEIN BIOCHEMIST

with immunological experience for immunofluorescence and immunoelectron microscopic investigations. Applicant should have doctorate and experience with poly- and monoclonal antibody techniques.

Send curriculum vitae, description of research interests, references to: Dr. Ernest Page, Department of Medicine, BH Box 137, The University of Chicago, 5841 South Maryland Avenue, Chicago, Illinois 60637. Equal Opportunity/Affirmative Action Employer. (NW45)A

POSITION OPEN

RESEARCH ASSOCIATE POSITION

Position available at the Research Associate level to work on the purification of lymphokines which regulate a B lymphocyte growth and differentiation. Applicants should possess a Ph.D. in a relevant field and have two or more years of postdoctoral experience. Familiarity with tissue culture methodology and commensurate with experience.

Send resumé and three letters of reference to:

Dr Peter Isakson
Box 448, Department of Pharmacology
University of Virginia Medical School
Charlottesville, Virginia 22908.

An Affirmative Action/Equal Opportunity Employer (NW50)A

M.R.C. CLINICAL RESEARCH CENTRE
(NORTHWICK PARK HOSPITAL)
WATFORD ROAD, HARROW
MIDDLESEX HA1 3UJ

NON-CLINICAL SCIENTIST

Applications are invited from post-doctoral microbiologists for a 3-year short-term appointment to study the host-parasite relationships between mammalian cells and bacteria, viruses and mycoplasmas. The research programme will be concerned with identification of glycoprotein or glycolipid receptors for infective agents on the host-cell membranes.

The successful candidate will join the Applied Immunochimistry Research Group headed by Dr Ten Feizi from whom further information can be obtained (Tel: 01-864 5311 ext. 2352).

Salary will be within the range £10,153-£16,158 (inclusive of London Weighting) depending on experience. Application forms are obtainable from Miss B. A. Shaw, Personnel Section, quoting reference 108/1/3905.

Closing date for applications 15th August 1985.

(7206)A

**University of Colorado
Health Sciences Center
Department of Biochemistry,
Biophysics and Genetics**

**Assistant Professor,
Molecular Biology**

Applications are sought to fill a tenure-track teaching/ research position in molecular biology, to begin on or about January 1, 1986. Candidates should have significant post-doctoral experience and will be selected primarily on the basis of their general qualifications.

To apply: send a vita, list of publications and the names and addresses of at least three references by October 15 to: Committee for Molecular Biology, B-121, University of Colorado Health Sciences Center, 4200 East Ninth Avenue, Denver, CO 80262.

The University of Colorado is an Affirmative Action/ Equal Opportunity Employer.

(NW66)A

**Postdoctoral Position in Cell and
Molecular Biology and Pharmacology**

Postdoctoral research position available to study the cell and molecular biology and pharmacology of arterial pressure control mechanisms in a collaborative interdisciplinary environment. Interests include molecular mechanisms of neurotransmitter storage and release, presynaptic regulation, and molecular mechanisms of cell signalling at neurovascular synapses including peptides, transmitters and receptor transduction. Projects provide opportunity for training with integrated facilities of transmission and scanning electron microscopy, cell culture, hybridoma technology, receptor techniques and molecular biology. Salary open with opportunity to progress to assistant professorship.

Interested candidates should send curriculum vitae and a brief statement of research objectives to: **Dr Thomas E. Gaffney, Chairman, Department of Pharmacology, Medical University of South Carolina, 171 Ashley Avenue, Charleston, South Carolina, 29425.**

(NW54)A

ANIMAL DISEASES RESEARCH ASSOCIATION

**Moredun Research Institute
Higher Scientific Officer (Immunologist/Virologist)
3 year appointment**

A 3 year appointment is available for a scientist with a PhD in Virology or Immunology to join a project investigating persistent viral infections. The successful candidate must be familiar with virological techniques and have an interest in the immunopathology of host responses to infection. Experience in immunochemistry and/or monoclonal antibody technology would be an advantage.

Salary scale: The current salary scale appropriate to the grade is: £7,788 rising by annual increments to £10,541. A non-contributory superannuation scheme is in force.

This is an equal opportunities post.

Further particulars may be obtained from **The Secretary, Animal Diseases Research Association, 408 Gilmerton Road, Edinburgh.** Closing date for receipt of completed application 1 September 1985.

Please quote reference 224/85 in all communications.

(7209)A

**THE INSTITUTE OF
CANCER RESEARCH**

Sutton, Surrey

**SENIOR TECHNICIAN
N HISTOLOGY**

(28 hours per week)

required to work with Pathologists and Scientists on aspects of human tumour diagnosis and complications of bone marrow transplantations. Previous experience in immunohistology is desirable. The successful candidate will be expected to handle frozen, paraffin and resin embedded material and to play a role in developing new techniques including in situ nucleic acid hybridization.

There is a close interaction between the Division of Pathology of the I.C.R. and the Department of Histopathology of The Royal Marsden Hospital.

Salary scale: £6,534-£7,802 (including Outer London weighting).

For further details contact: Dr J Sloane, Consultant Histopathologist, 01-643 5174 ext 24.

Applicants are advised that in the majority of The Institute's premises, smoking is prohibited.

Applications, in duplicate, with the names and addresses of two referees to be sent to The Personnel Officer, The Institute of Cancer Research, 17A Onslow Gardens, London SW7 3AL, quoting reference number 301/B/90.

Closing date: 8th August 1985.
(7203)A

**THE ANIMAL VIRUS
RESEARCH INSTITUTE**

SCIENTIFIC OFFICER

Applications are invited for the post of Scientific Officer to work in a group investigating the molecular biology of African Swine Fever virus. This virus contains a complex double-stranded DNA genome. The project involves analysis of the structure and function of the viral genome, using recombinant DNA methods and associated techniques. Collaboration with other groups within the Institute studying the immunology and pathogenicity of the virus is involved. The successful candidate will have a First or upper second class honours degree in a biological science, experience in molecular biology techniques is desirable.

Salary scale: £6,190 — £8,561.

22 days annual holiday, non-contributory superannuation and sickness benefit schemes. A house may be available for a suitable, married applicant.

Applications to include curriculum vitae and the names of two referees to be sent as soon as possible to the Secretary, The Animal Virus Research Institute, Ash Road, Pirbright, Woking, Surrey GU24 0NF. Tel: 0483 232441.

The Animal Virus Research Institute is an Equal Opportunity Employer. (7156)A

**UNIVERSITY OF
LIVERPOOL**

DEPARTMENT OF ORGANIC
CHEMISTRY

**SENIOR RESEARCH
ASSISTANT**

Applications are invited for a Post-doctoral Senior Research Assistant to work with Dr R. Cosstick in collaboration with Professor W. Fuller (University of Keele) on the effect of nucleoside analogues on DNA structure. The research involves the synthesis of polynucleotides using chemical and enzymatic techniques. Structural analysis of the polynucleotides will be performed by X-ray fibre diffraction using the SERC Synchrotron Radiation Source.

The post is best suited to a chemist or biochemist with an interest in DNA structure. The appointment will be for up to three years beginning as soon as possible after 1st October 1985.

Initial salary will be either £7,520 or £7,980 per annum (under review).

Applications, together with the names of three referees, should be received not later than 15 August, 1985, by the Registrar, The University, P.O. Box 147, Liverpool L69 3BX, from whom further particulars may be obtained. Quote Ref. RV/160/N. (7199)A

**POSTDOCTORAL
RESEARCH POSITION**

is available in Molecular Parasitology to study developmentally regulated proteins of the protozoan parasite Plasmodia. Strong background in recombinant DNA technology required. Starting salary \$20,000-\$25,000 based on experience. Position available now.

Applicants should send curriculum vitae and the names and addresses of three references to: Dr Donald F H Wallach, Director of Radiobiology Division, Tufts-New England Medical Center, 171 Harrison Avenue, Box 824, Boston, MA 02111. Tufts University is an Equal Opportunity/Affirmative Action Employer. (NW52)A

**THE LONDON HOSPITAL
MEDICAL COLLEGE
(University of London)**

**POST-DOCTORAL
RESEARCH FELLOW**

Post-Doctoral Research Fellow required for MRC Supported project, with Dr L Henderson, Psychology Department, Hatfield Polytechnic, on motor control in Parkinson's disease. The suitable candidate will probably have completed a PhD in experimental Psychology or a related field. The starting date is 1st October 1985. Salary within range £7,520 — £8,450 plus London Weighting of £1,233. Renewable for 3 years.

For further information and application to Dr C Kennard, Department of Neurology, The London Hospital, London E1 1BB (01-247-5454 ext 49). (7180)A

UNIVERSITY OF LONDON
British Postgraduate Medical
Federation Institute of
Orthopaedics
DEPARTMENT OF BIOMEDICAL
ENGINEERING
LECTURESHIP IN CELL
BIOLOGY

Applications are invited for the post of Lecturer in Cell Biology tenable from 1st October 1985. The successful candidate will have had post-doctoral research experience and be familiar with the use of scanning and transmission electron microscopy as applied to the physical and biological sciences. Practical experience in microanalysis, techniques used in the identification of metals in biological specimens is essential. The appointee will be expected to maintain and run an analytical electron microscopy suite which provides a central service facility for the Institute and outside users and co-ordinate an ongoing active research programme involving clinical practice and industry.

Salary commensurate with qualifications and experience on the Lecturer Scale — £7,520 — £14,925 per annum + London Weighting Allowance.

Application must be accompanied by a full curriculum vitae, statement of research interest, experience and the names of three referees. Forms from: The Secretary, Institute of Orthopaedics, (University of London) Brockley Hill, Stanmore, Middlesex HA7 4LP. 01-954-2300 Ext 779. Closing date for receipt of completed applications 20th August.

(7179)A

**IMPERIAL COLLEGE OF
SCIENCE AND
TECHNOLOGY**
LECTURESHIP OR SENIOR
LECTURESHIP IN
EXPERIMENTAL LASER
OPTICS

available in the Department of Physics. An established reputation in experimental laser physics, preferably in the area of ultra-fast phenomena, nonlinear optics, optoelectronics or optical information technology, is an essential prerequisite. Appointee will join the Laser Optics group and will be expected to pursue a vigorous experimental research programme, and to engage in postgraduate teaching for a Master's degree course in Applied Optics, in addition to general departmental teaching duties, research student supervision etc.

The appointment will date from 1 January 1986 (or as soon thereafter as possible). Salary according to age and experience on the Lecturer or Senior Lecturer scale (currently £7,520 to £14,135 to £17,705) plus London Allowance of £1,233.

Detailed applications, including CV, list of publications and the names of at least three referees should be sent to Professor T W B Kibble, FRs, The Blackett Laboratory, Imperial College, London SW7 2BZ by 20 September 1985.

(7180)A

UNIVERSITY OF WAIKATO
Hamilton, New Zealand
LECTURESHIP IN
BIOLOGICAL SCIENCES
(BOTANY)
A85/13

Applications are invited from suitably qualified persons for a lectureship in Botany within the Department of Biological Sciences. The Department has an establishment of 15 academic staff teaching general biology at first year and specialist courses in all major disciplines at second and subsequent years. Over 60 research students are currently enrolled for higher degrees in Biology (M.Sc. and D.Phil) with particularly active groups in animal physiology, microbiology, biochemistry, thermophilic enzymes, plant ecology and physiology and limnology.

The appointee will be required to assist in teaching general undergraduate plant biology as well as developing more advanced teaching in the area of his/her speciality.

Preference will be given to applicants who hold postgraduate qualifications and research experience in one of the following areas: plant breeding, quantitative plant biology and modelling of natural systems, or comparative plant morphology.

Prospects for collaborative research within the Department, and with the local Agriculture and Forestry research establishments, are excellent, and the successful applicant will be encouraged to develop research activities allied to these local strengths.

The current salary range for Lecturers is NZ\$23,622–NZ\$27,928 per annum.

Interested applicants should obtain further details from the Registrar, University of Waikato, Private Bag, Hamilton, New Zealand, or from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Equality of employment opportunity is University policy.

Applications close with the Registrar on 23 August 1985. (W2052)A

**ROYAL FREE HOSPITAL
SCHOOL OF MEDICINE**
(University of London)
Department of Neurological
Science
TECHNICIAN

required to work in an EM neuropathology laboratory. Applicants must have a minimum of 2 years experience in basic histological and/or cellular immunological techniques.

Salary on Whitley Council Scale £5,738 – £8,096 (under review) plus £1,042 London Weighting Allowance.

Further particulars and application forms are available from the School Office, RFHSM, Rowland Hill Street, London, NW3 2PF or telephone 01-794-0500 extn 4262. Please quote reference PKT/T. Closing date 9 August (7204)A

CSIRO
AUSTRALIA

CHIEF OF DIVISION

**DIVISION OF MINERAL PHYSICS
AND MINERALOGY
NORTH RYDE NSW**

Applications are invited for the position of Chief of the Division of Mineral Physics and Mineralogy. Candidates should have an established record of scientific achievement and leadership, and proven experience in the applications of research in the fields of mineral exploration (by geophysical or geochemical methods, including instrumentation) or other relevant scientific or industrial disciplines.

Mineral Physics and Mineralogy is one of the nine Divisions of the Institute of Energy and Earth Resources, CSIRO, which encompasses a broad spectrum of research activities and industrial applications in minerals, energy and water resources. Chiefs of Divisions are responsible to the Director of the Institute and are expected to contribute to the corporate planning and operation of the Institute.

The Division of Mineral Physics and Mineralogy is part of a major CSIRO centre at North Ryde, a suburb of Sydney, and has recently been reorganized by combination of the geophysics and geochemistry research groupings at that location. It has a total staff of approximately 102 of whom about 68 are professional graduates.

The work of the Division is closely linked to the needs of the Australian mineral exploration industry, including fossil fuels. Its research applies the principles and techniques of physics, geology, geochemistry, geobiology and mathematics to the identification and solution of problems in mineral exploration. Current research includes concepts, techniques and applications in airborne and satellite remote sensing, rock magnetism and electromagnetic techniques, hydrochemistry, geobiology, isotope geology, ore genesis and exploration geochemistry. The major proportion of the research is conducted in collaboration with Australian mining companies and commercialization of the Division's inventions and intellectual property is a feature of its operation.

The Division has substantial in-house computing and analytical equipment, which includes a rock magnetism laboratory, heavy ion accelerator facility, mass spectrometers and electron beam microprobe.

The Chief of the Division will be responsible for the leadership, management, integration and application of the research programs and will continue and further develop where practicable the collaboration with industry and other institutions. Management skills and organizational ability, particularly in internal and external communication and the motivation of staff at all levels, are required.

The salary for the position will be not less than \$57,307 per annum plus an expense of office allowance of \$1,355. For an exceptional candidate a salary up to \$64,143 plus allowance of \$1,900 per annum would be offered.

Appointment to CSIRO is for an indefinite period and carries Australian Government superannuation privileges, subject to normal conditions. The position of Chief of the Division is offered for a negotiable term of five to seven years, with subsequent options for a further term, if mutually desired, or for a senior position in the Organization.

The Executive of CSIRO has appointed a Search Committee to seek suitable candidates for this position. The Chairman of the Committee is Dr A. F. Reid, Director of the Institute of Energy and Earth Resources, who would be pleased to provide further information about the Division and discuss the position with potential applicants. He would also be pleased to receive advice concerning the appointment from people with a particular interest in it. Dr Reid may be contacted in Melbourne by telephone (03) 542-2432 or telex 35675.

Applications stating full personal and professional details, and names of at least three professional referees and quoting reference number A3917 should reach:

CSIRO IS AN EQUAL OPPORTUNITY EMPLOYER

(W2061)A

WESTERN AUSTRALIA
**RESEARCH OFFICER
 — SHEEP NUTRITION**

CONTRACT POSITION
 DEPARTMENT OF AGRICULTURE
POSITION NO. 006051

SALARY: AGRICULTURAL SCIENTIST — Level 1 \$A21,349–\$A28,306 per annum or Level 2 \$A29,921–\$A32,436 per annum.

VETERINARY SCIENTIST — Level 1 \$A23,564–\$A30,722 per annum or Level 2 \$A32,436–\$A35,183 per annum.

Salary dependent upon qualifications and experience.

QUALIFICATIONS AND EXPERIENCE: Bachelor of Science (Agriculture) or a degree in Veterinary Science or approved equivalent. At least 5 years' post graduate experience required for appointment to Level 2. Post graduate qualifications or equivalent through publication or research in equivalent through publication or research in scientific journals desirable. Research experience in the partitioning of nutrients between body tissues and/or nutrition-reproduction relationships desirable.

DUTIES: Undertake research into the influence or nutrition on the reproductive performance of ewes, with particular reference to ovulation rate.

CONDITIONS OF SERVICE: Appointee will be required to enter into a contract for 3 years. Four weeks' annual leave, cumulative sick leave entitlements and other general conditions applicable to Temporary Officers employed under the provisions of the Public Service Act, 1978.

TRANSPORT AND REMOVAL ASSISTANCE: The cost of economy class air fares incurred by the appointee, spouse and dependent children under the age of sixteen years (where applicable), plus a reasonable contribution towards the cost of transporting essential personal and household effects to Western Australia.

GENERAL: For further information contact:

 ARE BASED EXCLUSIVELY ON MERIT TO ENSURE
 EQUAL OPPORTUNITY FOR ALL. (W2067)A

UNIVERSITY OF
 EDINBURGH
 FACULTY OF MEDICINE
CHAIR OF PATHOLOGY

Applications are invited for the Chair of Pathology, which will fall vacant following the retirement of Professor Sir Alastair Currie on 31st March 1986. The Professor of Pathology will be expected to be of high academic standing, to have a wide interest in General Pathology, to have a substantial record of achievement in research, and to provide academic leadership as Head of the Department.

The Department has responsibilities for undergraduate teaching to medical and dental students, and for postgraduate teaching in the Faculty of Medicine. There is an Honours B.Sc. course in Pathology. The Department also has major responsibilities for the provision of diagnostic services to the National Health Service.

The salary will be at the clinical professorial level (£26,080 p.a.) if the successful candidate holds a registrable medical qualification or, if the successful candidate does not possess such a qualification, at the pre-clinical professorial level (minimum £18,555 p.a.); these salaries are under review.

Further particulars may be obtained from the Personnel Office, University of Edinburgh, 63 South Bridge, Edinburgh EH1 1LS, with whom applications (20 copies), including curriculum vitae and the names and addresses of three referees, should be lodged not later than 1st November 1985. Overseas candidates need submit only one copy of the application.

THE NATURE
 CONSERVANCY COUNCIL

SCIENTIFIC OFFICER:
 seabird colony register

The Nature Conservancy Council wishes to appoint an Ornithologist based at Aberdeen for a period of two years from early Autumn 1985.

The duties of the successful candidate will be to collate existing data on seabird breeding sites and to identify areas where further survey is needed. The appointee will liaise closely with members of voluntary ornithological and conservation societies, particularly the Seabird Group, and should be capable of co-ordinating work by large numbers of people. The work will be desk-based for most of the year, but some field-work will be involved in the summer. The post will be supervised by the Ornithologist in the Chief Scientist Directorate at Peterborough.

Qualifications and experience: The successful candidate should have a degree of equivalent in a biological or related subject and have experience of the use of computers. Ability to write computer programs and familiarity with seabirds would be advantageous. Applicants should have a current driving licence.

Salary: Dependant on qualifications and relevant experience: £6,190 rising to £8,561.

For further details and an application form, please contact Mr S. Woodfield, Personnel 1, Nature Conservancy Council, Northminster House, Peterborough PE1 1UA, to whom completed application forms should be returned by 15 August 1985.

The Nature Conservancy Council is an equal opportunity employer.

CSIRO
AUSTRALIA

**DROUGHT RESEARCH/
OCEAN-ATMOSPHERIC
MODELLING**

\$A26,001 — \$A38,243

**DIVISION OF ATMOSPHERIC RESEARCH
ASPENDALE VIC**

GENERAL: The Division of Atmospheric Research has a staff of 130 including 70 professional scientists and undertakes research into physical and chemical aspects of atmospheric phenomena and related areas: The Large Scale Dynamics program is concerned with the identification of mechanisms which determine the general circulation in the atmosphere and their impact on climate and its variability. A major new initiative in this program is the expansion of our effort in the investigation of the causes of widespread Australian droughts using large scale models of the atmosphere and ocean.

DUTIES: To undertake research development of a numerical model of the ocean which can be coupled with a similar atmospheric model to provide a wide ranging climate research facility. The appointee will, in collaboration with other members of the team, design and conduct innovative experiments to investigate anomalous behaviour of the atmosphere — ocean system and its impact on Australian climate. Interaction with other CSIRO Divisions and organizations with mutual interests would also be required.

QUALIFICATIONS: A PhD degree or equivalent qualifications in Applied Mathematics or Physics with demonstrated research ability in oceanography or dynamical meteorology. An interest in the interannual variability of the atmosphere-ocean system together with experience in numerical modelling of the ocean or atmosphere is desirable.

APPLICATIONS: Stating relevant personal particulars, including details of qualifications and experience, the names of at least two professional referees and quoting reference No A1146, should be directed to:

UNIVERSITY OF EDINBURGH
DEPARTMENT OF VETERINARY PATHOLOGY
WELLCOME TRUST LECTURESHIP IN MOLECULAR BIOLOGY

Applications are invited for a Wellcome Trust Lectureship in Molecular Biology in the Department of Veterinary Pathology, University of Edinburgh. The Department has a major interest and excellent facilities for basic research in immunology and the molecular aspects of pathology. The person appointed will join an active research group working on the immunology of persistent viral infection and will be expected to work on the molecular biology of pestiviruses (Border Disease virus of sheep, virus of Bovine Viral Diarrhoea — Mucosal Diseases of cattle) and investigate the molecular biology of the interactions between these viruses and the cells of immune systems in sheep. Molecular biology techniques have been introduced to the Department, and the successful applicant will be expected to further develop Molecular Biology in relation to the Department's research interests in immunology and its teaching programmes. Applicants must have research experience and a training in recombinant DNA technology and an interest in immunology.

The salary will be on the lecturers' scale (£7,190-£14,125). Starting salary depending on age, qualification and experience. The Lectureship is for three years in the first instance with renewal for a further two years on satisfactory review. Candidates should not be older than 35 years of age. Further particulars can be obtained from Professor I. McConnell, Department of Veterinary Pathology, University of Edinburgh, Summerhall, Edinburgh EH9 1QH (Tel: 031 667 1011 ext. 5322 or 5343). Candidates will be asked to submit a 500 word summary of the proposed research and should request the further particulars.

Applications (6 copies) giving the names of 3 referees should be sent to:

The Personnel Office, University of Edinburgh, 63 South Bridge, Edinburgh EH1 1LS.

Closing date for applications is 30th August, 1985, with appointment as soon as possible after that date. Applications from overseas should lodge their interest by this date with applications to follow.

Please quote reference 5266.

RESEARCH FELLOW

\$A26,001 — \$A32,083

DIVISION OF PLANT INDUSTRY CANBERRA ACT

CSIRO conducts scientific and technological research in laboratories located throughout Australia and employs about 7,500 staff, of whom some 2,900 are professional scientists. The Organization's research activities are grouped into five Institutes: Animal and Food Sciences, Biological Resources, Energy and Earth Resources, Industrial Technology and Physical Sciences. The CSIRO Division of Plant Industry is a member of the Institute of Biological Resources.

FIELD: Plant cell culture/somaclonal variation.

GENERAL: The CSIRO Division of Plant Industry conducts research on problems fundamental to plant biology and agricultural production. Prominent in this research are programs concerned with gene transfer and expression, cell culture, photosynthetic processes and nitrogen fixation.

The primary objective of this project is to produce lucerne (alfalfa) genotypes containing condensed tannins in their leaves. Such plants would result in increased utilization of dietary protein and reduced bloat in grazing ruminants.

DUTIES: The appointee will undertake research to produce monohaploid lucerne via microsporogenesis or induced parthenogenesis. Variation will then be generated in populations derived from haploid protoplasts. The appointee will collaborate closely with a cell culture group of 7 scientists. Closely related projects include somatic hybridization studies with lucerne protoplasts. Collaborations will also be with animal nutritionists and lucerne breeders.

QUALIFICATIONS. A PhD degree or equivalent qualifications in a relevant field and preferably with research experience in one or more of the following areas: cell protoplast culture, another culture, legume genetics.

TENURE: A term of 3 years with Australian Government superannuation benefits available.

APPLICATIONS: Stating relevant personal particulars, including details of qualifications and experience, the names of at least two professional referees and quoting reference No. Y7723, should be directed to:

CSIRO IS AN EQUAL OPPORTUNITY EMPLOYER

(W2060)A

POSITION ANNOUNCEMENT

The Department of Animal Science, Macdonald College of McGill University is seeking applicants for the position of

ASSISTANT PROFESSOR

in the area of

PHYSIOLOGICAL OR BIOCHEMICAL GENETICS

The appointment is a full-time, tenure track position. The successful candidate will be expected to develop a strong research program in an area of importance to animal science, such as regulation of growth, milk or egg production, or reproductive processes. The research should be complementary to ongoing programs within the Department in genetics, nutrition and reproductive physiology. A willingness to participate in interdisciplinary research projects and to teach in the areas of animal genetics and/or physiology at both undergraduate and graduate levels will also be expected. Qualifications include a Ph.D. in physiological or biochemical genetics with an orientation toward or experience in animal science. The base salary for an Assistant Professor is \$30,169. Closing date for applications is October 15, 1985 or until a suitable candidate is found. Interested applicants should send curriculum vitae and arrange for transcripts and at least three letters of reference to be sent directly to

Dr. Bruce R. Downey
Chairman, Department of Animal Science
Macdonald College of McGill University
21,111 Lakeshore Road

Ste. Anne de Bellevue

P.Q., Canada H9X 1C0

In accordance with Canadian Immigration requirements, this advertisement is directed to Canadian citizens and permanent residents of Canada.
(NW57)A

UNIVERSITY OF DUNDEE Department of Physiology RESEARCH ASSISTANT

Applications are invited from suitably qualified candidates for a Research Assistantship. The project, which is funded by the British Diabetic Association, is concerned with the control of transport into skeletal muscle and other tissues of amino acids and sugars in a variety of circumstances of health and disease. Tenure of the Research Assistantship will be for 2½ years. The successful candidate will be appointed on the Research Assistant IB scale starting at £6,600 up to £8,920. A possibility exists of registration for a higher degree. Candidates are invited to contact Professor M J Rennie (0382) 23181 extension 4572, who will supervise the project, for further particulars.

Applications (2 copies, or if airmailed from overseas, one copy) quoting reference EST/79/85J and containing full career details and the names of three referees should be lodged by 15th August 1985 with the Personnel Officer, The University, Dundee, DD1 4HN from whom further particulars are available
(7188)A

ST MARY'S HOSPITAL MEDICAL SCHOOL (University of London) Norfolk Place, London W2 1PG DEPARTMENT OF BIOCHEMISTRY POST-DOCTORAL RESEARCH ASSISTANT

Applications are invited for the above post to work on an MRC funded project on the microdissection and microcloning of the mouse X-chromosome. The project involves the construction of detailed molecular maps of individual regions of the mouse X-chromosome for the isolation and characterisation of interesting genetic loci, in particular mdx (X-linked muscular dystrophy). The applicant should have experience of recombinant DNA technology.

The post is available from 1 October 1985. Salary is on the 1A scale (starting point, £7,520 plus £1,233 pa London Allowance) for research staff.

Enquiries to Dr S. D. M. Brown, tel. (01) 723-1252 ext 333. Applications including full cv and names and addresses of 2 referees to Assistant Secretary (Personnel) at above address by 16 August 1985.

(7219)A

UNIVERSITY OF BIRMINGHAM

FACULTY OF MEDICINE AND DENTISTRY

DEPARTMENT OF RHEUMATOLOGY

RESEARCH FELLOW

Applications invited for a research fellow post, funded by MRC, to investigate the metabolism of iron by

MURDOCH UNIVERSITY Perth, Western Australia SCHOOL OF VETERINARY STUDIES LECTURESHIP IN MICROBIOLOGY

The appointee will be expected to teach general and pathogenic veterinary bacteriology, to develop a active research programme and to take part in the diagnostic microbiology service provided for clinicians. Training in bacteriology and a primary veterinary qualification would be preferred but the latter is not essential. Candidates with experience of training in contemporary molecular microbiology and/or immunology will be welcomed. Preference will be given to candidates with several years post-doctoral experience. (REF: 0453 — post available from January 1986).

General. Salary Range: \$A26,230 to \$A34,467 per annum (appointment will normally be made at the lower steps of the grade). This is a tenurable appointment and conditions include superannuation, long service leave, outside studies programme, payment of fares to Perth for appointee and dependent family removal and settling-in allowance and house purchase loan arrangement.

Procedure for applications: There is no prescribed application form but two complete sets of detailed applications, quoting the appropriate reference number, including full personal particulars, details of tertiary qualifications, career history with description of posts held, areas of special competence and interest research completed or currently being undertaken, personal views on teaching, membership of professional institutions or societies and positions of responsibility in these; list of relevant material published by the applicant, when available to take up appointment if offered and the names and addresses of three professional referees should reach the Personnel Officer, Murdoch University, Murdoch, Western Australia 6150, by 25 October 1985. Applicants should request the three professional referees to write immediately, quoting the appropriate reference number, to the Personnel Officer, Murdoch University, Murdoch Western Australia 6150. Applicants resident in the United Kingdom, Europe or Africa at the time of the application should also forward one further copy to: The Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.
(W2051)A

cells, and in particular the hepatocyte. Experience with tissue culture, immunological and/or biochemical techniques an advantage.

Salary on scale £7,520-£12,150 maximum starting £8,920 with superannuation for one year.

Further particulars Dr Stephen Young 021 472 1301 ext 3507

Applications (3 copies) to Assistant Registrar, Medical School, Birmingham B15 2TJ by 15 August 1985. Quote Reference RF/Rheum/SY (7222)A

YORK UNIVERSITY
DEPARTMENT OF EARTH AND
ATMOSPHERIC SCIENCE

**DYNAMIC
METEOROLOGIST**

The Department of Earth and Atmospheric Science at York University invites applicants for positions of University Research Fellow in the area of dynamic meteorology. The Fellowships are research positions funded by the Natural Sciences and Engineering Research Council (NSERC) at the level of Assistant Professor tenable for up to five years. It is expected that the successful candidates will be prime candidates for tenure stream appointments in the department as they become available in the next few years.

Further information can be obtained by contacting Prof. John C. McConnell, Chairman, Department of Earth & Atmospheric Science, York University, 4700 Keele Street, Downsview, Ontario M3J 1P3

These positions are tenable only by citizens or permanent residents of Canada at the time of application. In order to meet the NSERC deadline of 1st November, for fellowships to be awarded in 1986, York will require formal application by 30th September 1985. (NW49)A

**CHARING CROSS AND
WESTMINSTER MEDICAL
SCHOOL**

(University of London)

DEPARTMENT OF MEDICAL
ONCOLOGY

**BASIC GRADE
BIOCHEMIST**

Applications are invited for the post of Basic Grade Biochemist in the Department of Medical Oncology. The successful candidate will hold a degree in Biochemistry or related discipline and will work on an MRC-funded project using synthetic oligopeptides as immunogens for the production of anti-tumour antibodies.

Application forms available from The Secretary, Charing Cross and Westminster Medical School, The Reynolds Building, St Dunstan's Road, London W6 8RP, to be submitted within four weeks of the appearance of this advertisement. (7195)A

**AFRC INSTITUTE OF
ANIMAL PHYSIOLOGY**
Babraham Cambridge CB2 4AT
Two SENIOR SCIENTIFIC
OFFICER posts

Applications are invited for two New Initiative posts to work on regulation of animal cell growth. One post will be suitable for applicants trained in molecular biology and familiar with recombinant DNA technology including genomic library screening with oligonucleotide probes. The work will involve the characterisation of the genes for insulin-like growth factors. The second post will be for a cell biologist/biochemist to

**PUBLIC HEALTH
LABORATORY SERVICE**
CENTRAL PUBLIC HEALTH
LABORATORY
DIVISION OF ENTERIC
PATHOGENS
SENIOR GRADE
MICROBIOLOGIST

The Division is the National Reference Centre of Salmonella, Shigella and Escherichia coli, Vibrio and related organisms

The post holder will be involved in the investigation of the pathogenic mechanisms of these organisms.

Candidates should have a 1st or 2nd class honours degree in Microbiology and post-graduate experience is essential.

Further details from Dr S Scotland, ext. 3213.

Salary: £9,415-£12,173 plus £648 London Weighting

Closing date: 26th August 1985

For an application form and job description contact: Personnel Department, Central Public Health Laboratory, 61 Colindale Avenue, London NW9 5HT. Telephone: 01-200-4400. Please quote reference number DEP/2. (7197)A

**UNIVERSITY OF
NOTTINGHAM**

DEPARTMENTS OF
BIOCHEMISTRY AND SURGERY
POSTDOCTORAL OR
POSTGRADUATE
RESEARCH ASSISTANT

Applications are invited for the above post on a project funded by the Cancer Research Campaign to investigate biochemical and immunochemical aspects of glycoproteins produced by primary human breast cancers. The work will be carried out primarily in the Department of Biochemistry in close collaboration with Professor Blamey of the Department of Surgery. Initial salary will be up to fourth point on Range 1A for Research and Analogous Staff, depending on qualifications and experience.

Applications including a curriculum vitae and names of two referees should be submitted by August 1st to Professor F W Hemming, Department of Biochemistry, Queen's Medical Centre, Nottingham NG7 2UH (0602 700111 ext 3619). (7181)A

study the mechanism of action of these growth factors at the cellular level

The investigators will have support staff and will be expected to work in close collaboration with other scientists studying related areas. The appointments will normally be for three years with starting salary according to qualifications and experience within the pay scale £9,772 - £12,653 per annum. There is a non-contributory superannuation scheme. Application forms and further details are available from the Director's office quoting reference Phys/Bio/ST/NI. Closing date for applications 6th September 1985. (7189)A

**RESEARCH SCIENTIST/
SENIOR RESEARCH
SCIENTIST**

\$A26,001 — \$A38,243
DIVISION OF FOSSIL FUELS
NORTH RYDE NSW

FIELD Ash Formation During Coal Combustion

GENERAL: The Division of Fossil Fuels forms part of the Institute of Energy and Earth Resources. The Division has a leading reputation in the science and technology of coal utilization, including the combustion of coal in power generating systems.

The Division is currently expanding its research into the coal preparation, combustion, and environmental control aspects of the use of pulverized coal in power plants. Particular emphasis is being given to the nature of formation, and properties, of the ash formed during combustion from the inorganic species present in the coal. The aim of the research is to develop strategies, based on sound understanding of fundamental principles and of practical combustion systems, to reduce problems due to ashes that foul and corrode, or erode, boiler tubes, and to help develop improved systems for the control of particulate emissions. The Division is at present increasing its experimental facilities to study pulverized coal combustion under controlled conditions ranging from 'single particle' studies to the use of simulated power station flames. A person is sought who will use his/her established research ability to make a significant contribution to the understanding of the fundamentals of the combustion process, and who will provide a significant input to the development of the Division's combustion research.

DUTIES: The appointee will carry out research on the physico-chemical processes undergone by the inorganic constituents of coal during combustion, in order to understand the manner by which ash is formed, and how the process of formation might be modified. The appointee will join an existing team at an early stage of work on coal ash, and will be expected to develop a leading role in this area. He or she will be encouraged to develop an advanced theoretical as well as empirical, understanding of the ash-formation process. Advanced combustion and diagnostic equipment, and computational facilities, will be available for use and development, and access will be given to chemical and physical analytical facilities, including optical and electron microscopes.

QUALIFICATIONS: A PhD degree or equivalent qualifications in inorganic chemistry, metallurgy, or chemical engineering plus demonstrated research ability. Research experience in the behaviour of inorganic species at high temperatures, or in coal combustion, is desirable.

TENURE: Indefinite with Australian Government superannuation benefits available.

APPLICATIONS: Stating relevant personal particulars, including details of qualifications and experience, the names of at least two professional referees and quoting reference No A3975, should be directed to.

IMPERIAL CANCER RESEARCH FUND
RESEARCH FELLOWSHIP

Laboratory of Molecular Pharmacology — Edinburgh

A position is available for a Molecular Biologist/Biochemist in the Laboratory of Molecular Pharmacology with Dr C. R. Wolf, for studies into the molecular basis of Chemical-induced cancer. The successful candidate will be involved in establishing a programme on the isolation of human genes coding for proteins involved in the activation and/or deactivation of chemical carcinogens. The regulation of the genes, within these multigene families, with important functions in this regard will be studied. Polymorphisms within these genes will be investigated in relation to cancer susceptibility. Three year appointment. Salary range £8,920 to £11,205, entry according to qualification and experience.

For further information please telephone Dr Wolf on 031-667 1011 ext 2417.

Applications with C.V. and names and addresses of three referees should be sent to Ms S. M. Hurley, Imperial Cancer Research Fund, Lincoln's Inn Fields, WC2A 3PX, quoting ref. 96/85. (7223)A

CSIRO

RESEARCH FELLOW
PLANT PATHOLOGY
\$A26,001 — \$A32,083
DIVISION OF PLANT INDUSTRY
CANBERRA ACT

CSIRO conducts scientific and technological research in laboratories located throughout Australia and employs about 7,500 staff, of whom some 2,900 are professional scientists. The Organization's research activities are grouped into five Institutes: Animal and Food Sciences, Biological Resources, Energy and Earth Resources, Industrial Technology and Physical Sciences. The CSIRO Division of Plant Industry is a member of the Institute of Biological Resources.

GENERAL: The CSIRO Division of Plant Industry conducts research on problems fundamental to plant biology and agricultural production. One of the Division's programs involves research on viruses in plant rusts. The aims are to characterise these viruses using molecular techniques and to investigate the role these viruses may play in the development of rust disease. A new facet in this research is support from the Wheat Research Council to specifically investigate these viruses in wheat rusts and to develop probes for use in rust identification.

DUTIES: To undertake research on RNA viruses present in several different races and species of wheat rust.

QUALIFICATIONS: A PhD degree or equivalent qualifications with experience in the basic technologies of molecular biology. Experience with plant pathogens and/or double stranded RNA viruses would be an advantage.

TENURE: A term of 3 years with Australian Government superannuation benefits available.

APPLICATIONS: Stating relevant personal particulars, including details of qualifications and experience, the names of at least two professional referees and quoting reference No. E7725, should be directed to:

CSIRO AUSTRALIA

VIROLOGIST/ IMMUNOLOGIST

\$33,209 — \$45,083 pa

AUSTRALIAN NATIONAL ANIMAL HEALTH LABORATORY GEELONG VIC

The Australian National Animal Health Laboratory (ANAH) is a high security microbiological laboratory for the study of animal diseases exotic to Australia. It is located at Geelong, a city with population of 170,000 situated 80 kms south of Melbourne. Geelong offers an excellent lifestyle, with all the advantages of a major city in a semi-rural environment. Educational and recreational facilities are first class and ocean beaches are in easy range. When fully operational in 1985/86 it will employ a staff of 178, including 30 scientists.

ANAH plays an important role in diagnosis, research, training, and the development and testing of vaccines. There are currently four research groups within the Laboratory — Epidemiology, Molecular Virology, Pathogenesis and Immunity and Microbiological Security — which possess expertise in microbiology, immunology, veterinary pathology and molecular biology.

The Laboratory wishes to appoint a Virologist/Immunologist to the Epidemiology Group. The appointee will play a key role in the establishment of the Laboratory's capability for the diagnosis of exotic animal diseases; the Laboratory's research activities, particularly those aimed at improving diagnostic methods; and the training of field officers and laboratory staff in the diagnosis of exotic diseases

Applicants must possess a PhD degree or equivalent qualifications in microbiology or immunology and have a background of research experience and achievement in animal virology. A degree in Veterinary Science and eligibility for registration with the Veterinary Board of Victoria would be an advantage.

The appointee will spend one to three years in Thailand leading a small research team working on Foot-and-Mouth Disease soon after appointment.

Appointment is for an indefinite period and carries Australian Government superannuation benefits. Applications stating relevant personal and professional details, the names of at least three referees and quoting reference number A6760 should be directed to:

MOLECULAR BIOLOGIST

The University of Texas System Cancer Center,
Science Park — Research Division

Applications are invited for a faculty position (Assistant or Associate Professor level) in a multidisciplinary research laboratory studying cellular and molecular mechanisms of carcinogenesis. Research programs at Science Park, located in Buescher State Park, 40 miles east of Austin, include somatic cell genetics, DNA repair and mutagenesis, carcinogen metabolism and adduct formation, tumor promotion, virology, mechanisms of lymphomagenesis, normal and tumor cell differentiation, biochemical genetics and growth factors. Candidates would be expected to have or establish an independent research program. Preference will be given to individuals who have extensive expertise and commitment in the area of molecular biology. The Science Park provides competitive salary and benefits, a stimulating research environment, postdoctoral and graduate students, and opportunities for interaction with faculty at nearby institutions including the University of Texas Health Science Center in Houston, University of Texas at Austin, and Texas A & M University.

Interested applicants should send a complete curriculum vitae, the names of three references and a brief statement of research interests to:

Dr Thomas J. Slaga, Director, UTSCC, Science Park—Research

CHAIRMAN AND PROFESSOR Department of Horticultural Science Ontario Agricultural College UNIVERSITY OF GUELPH

Nominations and applications are invited for the position of Chairman of the Department of Horticultural Science at the University of Guelph, Guelph, Ontario, Canada. The position becomes available July 1, 1986. The department offers an undergraduate major in Horticultural Science and a graduate program at the Masters and Ph.D. levels. It currently has 18 faculty and 35 Graduate students.

The department chairman will have administrative responsibilities for the departmental programs; provide leadership to the faculty and assist them in professional development; maintain liaison with other administrators within the university, with government agencies and allied industry groups to co-ordinate research, teaching, and extension programs and strengthen interdisciplinary activities; actively seek and develop new sources of funding for the departmental programs and take an active part in professorial organizations. The position provides the opportunity to continue personal involvement in teaching, research and extension. Candidates must have demonstrated leadership and administrative ability.

Applications will be accepted until October 31, 1985. Applicants should submit a curriculum vitae and the names of three people who may be contacted for letters of reference to: Dr F. L. McEwen, Dean, OAC, University of Guelph, Guelph, Ontario, Canada N1G 2W1. (519-824-4120, Ext. 2284). (NW63)

ATTENTION SCIENTISTS AND RESEARCHERS

Posters are now being accepted for
BIO/TECHNOLOGY's premier conference

LOOKS TO THE NEXT DECADE

January 20-22, 1986, Clarion Hotel,
New Orleans

You are invited to submit abstracts of work with
commercial implications to:

Research Editor
BIO/TECHNOLOGY Conference
65 Bleecker Street, New York, NY 10012

Ideas suitable for support from corporate or venture
funding are particularly welcome.

Conference Themes:

- Day 1: The Molecular Biology of Plants & Animals
- Day 2: Commercial Production Processes
- Day 3: Innovations in Pharmaceuticals & Immunology

UMIST

DEPARTMENT OF CHEMICAL
ENGINEERINGNEW BLOOD
LECTURESHIPSURFACE AND COLLOID
SCIENCE

Applications are invited for the above "New Blood" post. The person appointed will be expected to contribute to the science base of a wide range of research activities including mineral beneficiation, crystallisation, membrane technology and biochemical engineering. Further developments in these areas are largely dependent on a greater awareness of surface chemistry in order to achieve rapid and fundamental progress. A willingness to develop such interdisciplinary collaboration will need to be demonstrated by the successful candidates. Background in physical chemistry, surface chemistry or colloid science desirable.

The appointment will commence on 1 October 1985 or as soon as possible thereafter. Commencing salary will be within the scale £7,520-£8,595 p.a. (under review). Requests for application forms and further particulars, quoting reference E/41, should be sent as soon as possible to the Establishment Section, Registrar's Department, Room B9, UMIST, P.O. Box 88, Manchester M60 1QB.

Informal enquiries to Professor J. Marsden, Head of Chemical Engineering Department, UMIST, 061-276-3311, ext 2106. (7212)A

RESEARCH FELLOW: Position available for postdoctoral research fellow in protein biochemistry to study the relationship between peptide sequence and functional interaction of proteins in hemostatic mechanisms. May also involve some immunology and electron microscopy. PhD with strong background in protein chemistry preferred. Joint appointment will be held in an appropriate department at Harvard Medical School. Send resumé with details and two references to Dr Henry Sawyer, Laboratory of Structural Molecular Biology, Dana-Farber Cancer Institute, 44 Binney St., Boston, MA 02115. An affirmative action/Equal Opportunity Employer. (NW53)A

POST-DOCTORAL FELLOW: Required to work in area of human thyroid autoimmunity with emphasis on T-cell cloning. Opportunity for independent work and career development. Prefer individual with T-cell background, marine or human. Position available Summer 1985. Send resumé to T. F. Davies, Mount Sinai School of Medicine, 1 Gustave L. Levy Place, New York, NY 10029. An equal opportunity employer. (NW64)

AT CANTERBURY ■ ■ ■ ■

Biological Laboratory

Two Postdoctoral Research
Fellows in Yeast Molecular
Biology

Applications are invited for two Postdoctoral Research Fellowships (scale RA1A) to be held from 1 October 1985, for three years, in the Biological Laboratory.

Post 1: (supervised by Dr M F Tuite) The successful applicant will be involved in a project to isolate and characterise genes coding for the subunits of the protein synthesis initiation factor eIF-2 from *Saccharomyces cerevisiae*.

Post 2: (supervised by Dr M F Tuite and Dr K Gull)

The successful applicant will use site-directed mutagenesis to engineer cytoskeletal proteins of *Saccharomyces cerevisiae*, with a view to defining specific structure-function relationships.

Both appointments are SERC funded and salary will commence at £7,980 (at present being reviewed). We are looking for applicants who have already obtained, or are in the process of submitting a PhD, and who preferably have a working knowledge of molecular biological techniques.

Applications (two copies) giving details of age, qualifications and experience, together with the names and addresses of two referees should be sent to the Assistant Registrar, Faculty of Natural Sciences, Chemical Laboratory, The University, CANTERBURY, Kent CT2 7NH by 2 August 1985. Please quote ref A49/85/N. (7205)E

UNIVERSITY OF
MANITOBADepartment of Oral Biology
POSTDOCTORAL
FELLOWSHIP

Applications are invited for a Postdoctoral Fellowship to investigate the mechanism of action of bioactive peptides (SP, VIP etc) in controlling exocrine secretion in submandibular gland cells. Initially the project will concern the role of phosphoinositides. Starting date, spring 1986. Salary, around \$23,000.

Applications, including a cv and the names of two referees, should be sent as soon as possible to: Dr N Fleming, Department of Oral Biology, University of Manitoba, 780 Bannatyne Avenue, Winnipeg, Canada R3E 0W3. (NW62)E

IMPERIAL CANCER
RESEARCH FUND
RESEARCH FELLOWSHIP

A post-doctoral, three year appointment is available in our Cellular Pharmacology and Antitumour Chemistry Laboratory, to work with Dr A Creighton on projects involving tumour therapy with antibody targeted radionuclides.

Salary range £10,285 to £12,570, entry according to qualifications and experience. Further details are available from Ms S M Hurley, Imperial Cancer Research Fund, Lincoln's Inn Fields, London, WC2A 3PX, telephone 01 242 0200 ext 305 quoting reference: 93/85 (7147)E

FELLOWSHIPS

EMBO

EUROPEAN MOLECULAR BIOLOGY ORGANIZATION
SHORT TERM FELLOWSHIPS
in molecular biology

The European Molecular Biology Organisation awards, to scientists working in Europe and Israel in the field of molecular biology and allied disciplines, short term fellowships of one week up to three months duration. The fellowships are to support collaborative research between laboratories in different countries and provide a travel grant and subsistence allowance. Applications may be made at any time and are decided upon soon after the receipt of application.

Applications for exchanges between laboratories within any one country cannot be considered. Fellowships involving transatlantic travel are awarded only in extremely exceptional circumstances.

Application forms and further details may be obtained from Dr J. Tooze, Executive Secretary, European Molecular Biology Organization, 69 Heidelberg 1, Postfach 1022 40, F.R.G. (W1577)E

UNIVERSITY OF
NOTTINGHAM
MEDICAL SCHOOLDEPARTMENT OF
BIOCHEMISTRYPOST-DOCTORAL
FELLOW

Applications are invited for a research fellowship financed by the British Heart Foundation for a study of phosphoinositide metabolism and the molecular mechanisms mediating the responses of cardiac muscarinic receptors. The fellowship is tenable for two years initially from 1st October, 1985 at a starting salary of £7,980 or £8,450 depending on age and experience. Membership of USS included.

Applicants should send curriculum vitae and the names of two referees to Professor J N Hawthorne, Department of Biochemistry, Medical School, Queen's Medical Centre, Nottingham NG7 2UH, from whom further details may be obtained (telephone: 0602-700111 Ext 3488). Closing date 31st August, 1985.

(7065)A

UNIVERSITY OF WARWICK
POSTDOCTORAL
RESEARCH FELLOWSHIP
IN BIOLOGICAL SCIENCES

Applications are invited for an MRC-funded Postdoctoral Research Fellowship to join Dr Elizabeth Jones and Professor Hugh Woodland (MRC Animal Development Group) on a project involving the production of a panel of monoclonal antibodies to tissue-specific markers identifying the main embryonic tissues of the amphibian neurula. The antibodies produced will be used to study the cell biology of early cell determination. The candidate should have experience in tissue culture, preferably in hybridoma technology, or in developmental biology.

The position is for three years commencing October 1985 on the Research IA scale: £7,520 to £12,150 p.a. Applicants should send a C.V. (including a full list of publications) with the names and addresses of two referees to the Executive Officer, Department of Biological Sciences, University of Warwick, Coventry CV4 7AL, quoting reference EAJ/HRW/NAR. Further information can be obtained by ringing 0203-240111 ext. 6015.

Closing date. 8th August 1985.

(7196)E

EMBO
European Molecular Biology Organization
LONG TERM FELLOWSHIPS IN
MOLECULAR BIOLOGY
Autumn 1985 - Awards
Next deadline: 15 August 1985

EMBO long term post-doctoral fellowships are awarded to promote the development of molecular biology and allied research in Europe and Israel. To be eligible a candidate must hold a doctorate degree and the exchange must involve a laboratory in Western Europe or Israel. EMBO fellowships are not, however, awarded for exchanges between laboratories within any one country. Long term fellowships are awarded initially for one year, but depending on a review of progress, they may be renewed for a second year. In cases of exceptional scientific merit renewal for a third year is possible. The fellowship comprises a return travel allowance for the fellow and any dependents and a stipend and dependents' allowance.

Since the selection procedure may include an interview, candidates are requested to respect the deadline for complete applications which is 15 August 1985. Successful candidates will be notified of their awards immediately after the meeting of the selection committee, which is on 21 October 1985.

Application forms and further details may be obtained from Dr J. Tooze, Executive Secretary, European Molecular Biology Organization, Postfach 1022.40, 69 Heidelberg 1, F. R. Germany. (W1893)E

SEMINARS & SYMPOSIA

The 6th CIRD SYMPOSIUM

"ADVANCES IN SKIN PHARMACOLOGY"

will be held at Sophia Antipolis, near Cannes
FRIDAY, OCTOBER 4 – SUNDAY, OCTOBER 6, 1985

TOXICITY AFTER TROPICAL APPLICATION

The cutaneous toxic effects of drugs applied to the skin will be evaluated. Aspects of percutaneous drug absorption as well as the biochemical consequences and side effects will be given prominence.

Friday Afternoon: In vitro Studies: Carcinogenesis

Marks, F. (Heidelberg), Gielen, J. (Liège), Bickers, D. (Cleveland), Chouroulinkov (Villejuif).

Saturday Morning: Animal Toxicology

Kemper, F. (Münster), Lombard, A. (Evreux), Oliver, G. (Macclesfield), Friedmann, J. C. (Paris).

Saturday Afternoon: Clinical Aspects including Penetration and Systemic Toxicity

Zesch, A. (Berlin), Schaefer, H. (CIRD), Maibach, H. (San Francisco), Lowe, N. (Los Angeles), Kligman, A. M. (Philadelphia).

Sunday Morning: In vitro Studies: Cytotoxicity in General

Reichert, U. (CIRD), Dunkel, V. C. (Washington, DC), Gilchrist, B. (Boston), Bernstein, I. A. (Ann Arbor).

For further information please write to Professor Hans Schaefer, Centre International de Recherches Dermatologiques, Sophia Antipolis, F-06565 Valbonne, France.

ASSISTANTSHIPS

**UNIVERSITY OF HULL
 DEPARTMENT OF CHEMISTRY
 BP Extramural Research Award
 POSTDOCTORAL
 RESEARCH
 ASSISTANTSHIP IN
 SURFACE CHEMISTRY**

Applications are invited for the above post, initially for 1 year from an agreed starting date, to work with Dr R Aveyard on a project concerned with surfactant adsorption onto solids in oil + water systems exhibiting ultralow interfacial tensions, in connection with BP's interest in improved oil recovery. The group at Hull working under BP sponsorship will consist of 2 postdoctoral assistants and a PhD student. Applicants should have experience in colloid and/or surface chemistry.

The commencing salary will be in the range £7,520 — £9,390 per annum (under review) on the 1A scale for Research and Analogous Staff, depending on age and experience, plus USS benefits. Applications, together with the names of two referees and curriculum vitae, should be sent direct to Dr R Aveyard, Department of Chemistry, The University, Hull, HU6 7RX. (7184)P

**UNIVERSITY OF
 WARWICK**

**RESEARCH ASSISTANT IN
 BIOLOGICAL SCIENCES**

Applications are invited for an AFRC-funded Research Assistantship to work on a project concerning the molecular virological characterisation of rotaviruses. Applicants should hold a minimum upper-second class Honours degree, preferably with two years' postgraduate experience and be able to work independently. The successful applicant will not be eligible to register to work for a higher degree.

The position is for three years, commencing as soon as possible, on the research 1B scale: £6,600 to £8,920 p.a. Applicants should send a C.V. with the names and addresses of two referees, to the Executive Officer, Department of Biological Sciences, University of Warwick, Coventry CV4 7AL, quoting reference MAM/BS604. Closing date 15th August 1985. (7228)P

STUDENTSHIPS

**THE UNITED MEDICAL
 AND DENTAL SCHOOLS**

ST THOMAS'S CAMPUS

**STUDENTSHIP IN
 PHYSIOLOGY**

A Medical Research Council Studentship is available at the Sherrington School of Physiology. Applicants with a good degree in Physiology or related subjects should write with full curriculum vitae to Professor A. Taylor, Sherrington School of Physiology, St Thomas's Hospital Medical School, London SE1 7EH (tel. 01-928 9292 ext 2241) from whom further details are available. (7198)F

**PHARMACEUTICAL
 SCIENCES INSTITUTE**

ASTON UNIVERSITY

**CANCER RESEARCH
 CAMPAIGN**

**EXPERIMENTAL
 CHEMOTHERAPY GROUP**

**THREE RESEARCH
 STUDENTSHIPS**

are vacant immediately within this large, multi-disciplinary research group, funded by the Cancer Research Campaign.

(1) Study of the metabolism and mechanisms of hepatotoxicity of the anti-tumour agent N-methylformamide (Dr A. Gescher).

(2) Investigation of the effects of alkylating agents on the plasma membrane $\text{Na}^+\text{K}^+\text{Cl}^-$ cotransporter and its role in the control of proliferation (Dr J. A. Hickman).

(3) Biochemical investigation of factors responsible for weight loss in cancer (Dr M. J. Tisdale).

Candidates should have been awarded a first or upper second class honours degree in biochemistry, physiology, pharmacology or a related science. Enquiries should be made without delay to the CRC Experimental Chemotherapy Group, Aston University, Birmingham B4 7ET (021 359 3611, ext. 4175) (7202)F

CONFERENCES & COURSES

**COMBUSTION
 FUNDAMENTALS**

A one week course of post experience lectures will be held at IMPERIAL COLLEGE from 23rd to 27th September 1985.

Details from Professor F. J. Weinberg FRS, Department of Chemical Engineering & Chemical Technology, Imperial College, London SW7 2BY. Telephone: 01-589-5111 ext. 4360/4498. (7225)C

APPTS. WTD

**THE ROWETT RESEARCH
 INSTITUTE**

Bucksburn, Aberdeen AB25

**RESEARCH
 STUDENTSHIPS**

(2 posts)

Applications are invited for Studentships leading to a PhD (Abercrombie University).

1. Research into the factors which influence rumen development and hence intake of dry feed young calves. This project, sponsored by British Sugars PLC, will investigate how the physiological/chemical mechanisms of the developing rumen respond to change the nature of the carbohydrate source supplied in weaner ration.

2. Research on in vitro systems of predicting nutrient digestibility feeds for pigs. This project, sponsored by external funds, involves the development of suitable chemical and biochemical techniques estimating the availability of nutrients in compound feeds for growing and adult animals.

Candidates for both positions should possess a first or upper second class honours degree in agricultural biochemistry, animal nutrition or related subjects.

Applications, including CV the names of two referees should be addressed to the Secretary, Rowett Research Institute, Bucksburn, Aberdeen AB2 9SB, from whom further details can be obtained.

Closing date 8th August 1985. (7207)

BETA SEPHAROSE*

For purification of Beta Interferon

Celltech. First to market monoclonal antibody-based reagents for purification and assay of Gamma and Alpha Interferons.

Now, first again with Beta Sepharose* for the purification of Beta Interferon.

The latest addition to our range of monoclonal antibody-based purification reagents, Beta Sepharose,* has been developed especially for industrial scale purification. For the first time, high yields of high purity Beta Interferon are achievable from a commercially available single step process.

Contact David Senior now for a sample and information.

JUPITER'S GOSSAMER RING

No other densitometer looks bigger and better

Big enough to handle whatever electrophoresis gels you're using. With better results to match your work. That's LKB's new laser densitometer. UltraScan XL looks at all types and formats, up to 22×25 cm, wet or dried. With increased capacity and faster scanning, this big all-rounder gets more work done in a lot less time. And its straight-as-a-laser beam delivers an unrivalled $50 \mu\text{m}$ resolution with a linear range of 4 OD. Now you can really penetrate closely stacked bands and uncover a wealth of data. Multiple scanning of every sample track gives you reliable average measurement across each protein zone. And when you want fast quantitation by simple programming, the onboard integrator delivers. The scan together with area calculations are presented directly to a standard dot matrix printer. It couldn't look better.

But don't be deceived by good looks alone. UltraScan XL comes with brains as well. The onboard computer lets you exactly define track position and fields of interest, and then automatically scans up to 99 tracks – any way you decide. With gels containing zones of varying intensities from track to track, the unique normalization program lets you compare all your samples in just one run. And talking about comparison, take a look at the large screen monitor. Just tell UltraScan XL what you want, and your video shows you every decision, every command and even a few wishes. Like interfacing with your favourite computer. Or running your own software. You'll evaluate, store, manipulate, display and present your results better than ever.

All in all, it looks like you're getting yourself a scanner that's bigger and better from every viewpoint. Style. Performance. Value. It's worth looking at. Today!

Over 60 qualified representatives throughout the world.

An Important Announcement.

This year is the 10th Anniversary of Olympus Optical (UK) Co. Limited. During this decade, Olympus has sold more 35mm cameras in this country than any other company.

Olympus also distributes the Pearlcorde personal Microcassette recording system™ and a complete video photography system. Olympus is an established and successful manufacturer worldwide in these markets.

Olympus is also in the forefront in the highly technical specialist product areas of microscopes and endoscopes, in both the industrial and medical fields.

Due to extensive growth in sales and the extension of the product range in these specialist markets, Olympus is delighted to announce that from 1st November 1985, a new operating company is being established to handle future development of Olympus biological and metallurgical microscopes.

As a result of this a number of job opportunities will be created for people with the right level of specialist experience.

If you would like to become part of the Olympus team for the future and have the right background, then the following opportunities are now available to you.

Olympus Microscope Division is seeking to employ: Marketing Manager. Sales Managers and Representatives. Sales Administration Staff. Sales Support Personnel and Service Engineers.

The benefits will include competitive salaries, an annual bonus, BUPA and non-contributory pension scheme.

Please write sending full career details to:
Mrs. VJ. Rockel, Olympus Optical Co. (U.K.) Limited,
2-8 Honduras Street, London EC1Y 0TX.

Biopolymer problems?

No problem with Varian HPLC.

Post-Column Derivatization

Hydrolysate and physiological fluid analysis. Ninhydrin and OPA chemistries. Fully automated systems for dedicated amino acid analysis.

Pre-Column Derivatization

Rapid analysis. Subpicomole sensitivity. Stable derivatives. Simultaneous analysis of primary and secondary amino acids.

Protein Purification

Full spectrum of MicroPak™ TSK size exclusion, ion exchange, reversed phase, and hydrophobic interaction columns for every application.

Peptide Mapping

Best sensitivity with high efficiency columns, state-of-the-art detectors. Microbore HPLC sample-limited applications and peptide concentration.

PTH Amino Acid Analysis

Rapid resolution on MicroPak PTH-AA Columns. Subpicomole sensitivity with microbore HF.

Oligonucleotide Purification

Rapid, high-resolution separation of deprotected oligonucleotides on the MicroPak SP-oligonucleotide column.

Nature® (ISSN 0028-0836) is published weekly on Thursday, except the last week in December, by Macmillan Journals Ltd and includes the Annual Index (mailed in February). Annual subscription for USA and Canada US \$230. USA and Canadian orders only to: *Nature*, Subscription Dept, PO Box 1501, Neptune, New Jersey 07753, USA. All other orders to *Nature*, Brunel Road, Basingstoke, Hants RG21 2XS, UK. Second class postage paid at New York, NY 10012 and additional mailing offices. Authorization to photocopy material for internal or personal use, or the internal or personal use of specific clients, is granted by *Nature* to libraries and other users registered with the Copyright Clearance Center (CCC) Transactional Reporting Service, provided that the base fee of \$1.00 per copy plus \$0.10 per page is paid directly to CCC, 21 Congress Street, Salem, Massachusetts 01970, USA. The identification code for *Nature* is 0028-0836/85 \$1.00 + \$0.10. US Postmaster send address changes to: *Nature*, 65 Bleeker Street, New York, NY 10012. Published in Japan by Macmillan Shuppan K.K., 5th Floor Eikow Building, 1-10-9 Hongo, Bunkyo-ku, Tokyo, Japan. © 1985 Macmillan Journals Ltd.

Hot on delivery...

...cold on arrival

When you order molecular biologicals from Pharmacia you'll find we're pretty hot on delivery.

We'll dispatch your order as soon as we get it, packing it carefully in wet or dry ice.

Now our enzymes are supplied in screw cap mini vials with new waterproof labels, and will easily fit into your centrifuge

tubes and freezer trays.

At Pharmacia Molecular Biology Division that's all part of the service. We realize that the success of an experiment depends on the quality of the products used and the speed at which you get them. With us you'll find that the only thing kept on ice is your product - not your

experiment.

Contact us today and we'll send you our free catalogue with details of over 800 molecular biologicals.

Pharmacia... your partner in molecular biology.

LASER ANNIVERSARY
SPECIAL ISSUE

- X-ray lasers
- Optical computers
- Lasers in biology and medicine
- The birth of masers and lasers

These and other topics are addressed in Nature's special Laser issue which marks the 25th anniversary of T. H. Maiman's report on the first working laser (Nature August 6th 1960). Extra copies of this issue are available now from the address given below — price as for back copies

—GUIDE TO AUTHORS—

Authors should be aware of the diversity of Nature's readership and should strive to be as widely understood as possible

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable)

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an italic heading of about 50 words

Letters to Nature are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are

Matters arising are brief comments (up to 500 words) on articles and letters recently published in Nature. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted

Manuscripts may be submitted either to London or Washington. Manuscripts should be typed (double spacing) on one side of the paper only. Four copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc, should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc, should be identified on one copy of the manuscript at their first appearance

References should appear sequentially indicated by superscripts, in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963-65). The first and last page numbers of each reference should be cited. Reference to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published

NEW TITLES IN THE TOPICS IN MOLECULAR AND STRUCTURAL BIOLOGY SERIES

Series editors: Watson Fuller, Department of Physics, University of Keele
Stephen Neidle, Department of Biophysics, Kings College, London
Tony Atkinson, Microbial Technology Laboratory, PHLS Centre for Applied Microbiology and Research, Salisbury

Volume 5 **Connective Tissue Matrix**

D. W. L. Hukins, Department of Medical Biophysics, University of Manchester

An introductory chapter details individual macromolecular components and following chapters are concerned with interacting systems of macromolecules in extracellular matrices and the ways in which they influence the mechanical, and hence biological, functions of connective tissue

1984 256pp 0 333 33372 1 £35

Volume 6 **Metalloproteins; Part One – Metal Proteins with Redox Roles**

P. M. Harrison, Department of Biochemistry, University of Sheffield

Metals play important roles in a large number of biochemical reactions. These volumes explore those aspects of biochemistry which involve association of metal with protein. The metals concerned, principally iron, copper and molybdenum, belong to the transition metal series

March 1985 272pp 0 333 33374 8 £35

Volume 7 **Metalloproteins; Part Two – Metal Proteins with Non-Redox Roles**

P. M. Harrison

This second volume on metalloproteins brings together six classes of protein to illustrate a variety of important physiological processes in which metals are involved in association with protein

March 1985 352pp 0 333 33375 6 £45

Volume 8 **Polysaccharides: Structure and Function**

E. D. T. Atkins, H. H. Wills Physics Laboratory, University of Bristol

Polysaccharides are a group of complex carbohydrates including starch and cellulose, that are involved in a variety of ways in the structure and function of organisms. This book aims to review recent advances in the understanding of the structure of the major types of polysaccharide, stressing those of medical, biological and economic importance

October 1985 250pp 0 333 33371 3 £35

Volume 9 **Topics in Nucleic Acid Structure, Part 3**

Stephen Neidle, Department of Biophysics, University of London

Forthcoming 1986 256pp 0 333 33376 4 £35

Negotiating a test-ban treaty

The new-found excitement about a comprehensive test-ban treaty is premature. There are technical and military difficulties still to be surmounted.

THE fortieth anniversary of the Hiroshima explosion has seen an unexpected revival of interest in the notion that the testing of nuclear weapons might be banned altogether. Indeed, Mr Mikhail Gorbachev, the Soviet leader, some weeks ago announced a unilateral moratorium on testing even within the limits now allowed by treaty (only underground, and only with weapons yielding less than the equivalent of 150,000 tonnes of TNT). Mr Gorbachev also says that the Soviet Union will extend the moratorium indefinitely if the United States will only agree to follow suit. The new-found popularity of the comprehensive test-ban has been further emphasized by Sir Geoffrey Howe, the British Foreign Secretary, who was saying at the end of last month at Helsinki that the British government would be happy with a test-ban if only it could be properly policed. The only discordant note has come from the United States, where spokesmen in Washington have taken the line that a test-ban could not at present be monitored securely, for which reason the Soviet offer must be regarded as a kind of trap. As on many other recent attempts to make progress with arms control, everybody is half-right and, at the same time, half-wrong.

There are two reasons why the comprehensive test-ban has sprung to prominence just now. At the end of this month, the third review conference of the Non-Proliferation Treaty (NPT) will begin at Geneva, and the non-nuclear powers that have signed the treaty will be upbraiding the nuclear powers for having done so little, these past fifteen years (since the treaty came into force), to negotiate measures to limit strategic arms. The Soviet Union can hope to fend off at least some of the criticism by pointing to Mr Gorbachev's offer. Soon afterwards, in November, Mr Gorbachev and President Ronald Reagan will be meeting again at Geneva; the former is certain to ask the latter why the United States will not agree to a comprehensive test-ban treaty. Both sides had better acknowledge in advance that the issue between them will not be simply settled. In many ways, the technical problems are not the most obdurate.

Workable

Close on seven years ago, the three signatories of the threshold test-ban treaty, Britain, the Soviet Union and the United States, had all but settled the terms of a workable treaty. Then, as now, it was plain that a comprehensive treaty cannot be verified by the recording of seismic signals picked up by seismographs located entirely outside the territory of the signatories to such a treaty, whence the sensible technical compromise that signatories should each provide houseroom for ten remotely operated seismic stations on their own territory. The haggle that had arisen during the negotiations of this draft treaty about the suspicion that such stations might be used for more general espionage were eventually resolved, apparently amicably, by the US suggestion that public-key cryptography could be used to provide security; the host country would be able to decode messages, but would be unable (lacking the encoding key) to corrupt them with false information. It may be that, on reflection, the United States doubts the validity of these solutions, but there is no reason to fear that the problems tackled seven years ago are not soluble in one way or another, perhaps by refining the network of observing stations, perhaps by more elaborate ways of making the transmission of information secure. (The absurd Soviet demand that there should be ten seismic stations

in the United Kingdom and its possessions is a different kind of stumbling-block, but one that is, as it was, negotiable.) What is lacking now is the enthusiasm for a comprehensive test-ban.

What has gone wrong? The Soviet Union appears to have forgotten that the eagerness of the United States to conclude further arms control agreements had waned long before the present US administration came to power at the beginning of 1981, and that the decisive Soviet influence over Afghanistan was as much responsible as President Carter's recognition, during his last year in office, that it would not be possible to force the SALT II agreement through the US Congress. Since then, East-West relations have further deteriorated, both in rhetoric and by the evidence of events. During the same period, the United States has made the painful discovery that the single new strategic missile allowed by the SALT II treaty, the MX missile, is too clumsy an object for security, and has also argued loudly (if mistakenly) that it should be possible to avoid the threat of nuclear attack, and also of the need of specific arms control agreements, by means of a defence against ballistic missiles. The Soviet Union may say "bad luck!" on the first score and be sceptical to the point of hostile disbelief on the second, but it must also know that two sovereign states can be made to conclude a treaty only if each should voluntarily have concluded that its own interests will be advanced by whatever surrender of sovereignty is entailed.

Unpropitious

There are other reasons why the present time is not propitious for a comprehensive test-ban treaty. With the passage of almost a decade since negotiations on the existing draft began, nuclear powers not party to the negotiations, France and China specifically, have become a decade more sophisticated. China's accumulation of nuclear explosives has probably been proportional to the time elapsed, but China has no plutonium warheads as things are; the chances that such a power would sign a comprehensive test-ban treaty are small, which should give the Soviet Union pause. France is less of an immediate problem, but cannot entirely be ignored. None of this implies that these two nuclear powers should be left entirely to their own ambitions, but the process of discovering where they stand cannot be accomplished by the issuing of public challenges by one superpower to the other.

Another reason why the test-ban treaty is more than a matter on which all people of good intentions should instinctively agree turns on the uncertainty that would inevitably be engendered among the military people, and thus among politicians in both East and West, if the testing of nuclear weapons were suddenly outlawed. Will those warheads function as we designed them? Quite apart from the nuclear explosives, will the other components still do their job? A test-ban treaty would be quickly followed by the development of techniques for the near-testing of nuclear weapons, but uncertainty about the function of existing stockpiles would persist. That is why, in present circumstances, a comprehensive test-ban treaty is attainable only as part of a larger package, involving a substantial reduction of the numbers of warheads deployed by the two superpowers. The occasion to look for such an agreement is not next November's summit but the bilateral negotiations that will have resumed a good two months earlier. □

Vaccine-damage damage

A scheme to compensate for vaccine-damage in the United States must be delayed no further.

WHEN and how should individuals be compensated for injuries they suffer in the interests of the public good? This is the question underlying the thoughtful report last week from the Institute of Medicine in the United States, grappling yet again with the question of how the occasional injuries caused by vaccination should be dealt with (see p.476). The rationale of mass vaccination programmes is that the treatment of individuals will not merely protect them against an infection but also help break the chain of infection in the population at large. There are by now many spectacular illustrations of the success of vaccination, the chief agent in the eradication of smallpox and the reduction of the incidence of the damaging paediatric infections, at least in the industrialized countries of the world.

But vaccines are not free from risk. Even when properly manufactured, they may damage those who look to them for protection. The Sanford committee catalogues the social and legal anomalies occasioned by this ironical contradiction, advocating a statutory compensation scheme for those affected. In doing so it follows a long line of private organizations that have urged the need of similar arrangements (already in place, on a modest scale, in California). For at least the past three years, the US Congress has been grappling in a desultory fashion with legislation designed to give effect to such a proposal; in the Senate, the chief sponsor has been Senator Paula Hawkins, in the House of Representatives, Mr Henry Waxman and Mr Edward R. Madigan have taken the lead. The sponsorship is far from negligible; why has nothing happened?

The difficulty seems to be that all the participants in the administration of vaccination programmes and their consequences are ambivalent. Manufacturers of vaccines seek above all to escape from the present uncertainty, in which they (and their insurers) cannot guess in advance the monetary scale on which they might be liable if a vaccine should provoke a rash of lawsuits, but would not wish to go so far as to become subcontractors for some agency of the US government, which might then become the sole source of vaccines and the one responsible for compensation. The federal government, although anxious that vaccination programmes should not be hamstrung as at present, is similarly concerned about the cost (witness its experience with the epidemic of swine influenza that never came, in 1976) and the implication that this small corner of medicine might be "socialized". Physicians who administer vaccines, solicitous for their patients, have an interest in seeing that manufacturers and not themselves are usually held responsible for accidents. Can practising, as distinct from academic, lawyers have an interest that the present jungle of the courts should be perpetuated?

The resolution of these conflicting interests should be much easier than the Institute of Medicine allows. What seems to frighten everybody is the high cost of settling damage suits in the US courts (or in the corridors around them) and the difficulty, apparently often equated with constitutional impropriety, of interfering with the law of tort which allows an injured person to sue whoever may be responsible. But it is now made clear that in the settlement of vaccine damage suits, the amount of compensation paid to those who are tragically injured, or to their relatives, will often include a large element intended to compensate for "pain and suffering" occasioned by the accident. It is right and proper that manufacturers distributing defective vaccines should be sued for whatever the courts will award, but otherwise, given that the risks of vaccination are in any case not negligible, but that those consenting to vaccination do so in the expectation of personal immunity from some infection, it would be more equitable than the present system that the right to sue should be replaced by the right to administrative compensation, provided that the system offered as an alternative is both speedy and sufficient to cover money losses, medical expenses and support for dependants, for example. The Sanford committee

might usefully have grasped this nettle. It should also have pointed out that its useful compilation of vaccine-damage schemes in place elsewhere than the United States is not as valuable a guide as it may seem; the British scheme, for example, which limits administrative compensation to £10,000 but which does not extinguish the right to sue the manufacturer of a vaccine, is more generous than it may seem because of the free care provided by the National Health Service for those who may be damaged.

So why shrink from meddling with the law of tort in the United States? Vested interests (those of the lawyers and of the litigious) apart, one of the chief inhibitions seems to be the knowledge that the whole apparatus of case-law on product liability built up by the US courts would be undermined by the acknowledgement that a person's right to compensation would be mitigated by the expectation that the purchase of a disputed product would ordinarily be beneficial. Provided that the purchaser knows that there are also risks, the doctrine is equitable; but plainly it also applies to products other than vaccines, pharmaceuticals for example. And when there is public as well as private benefit involved, it is not merely necessary but desirable that the state, or the federal government in the United States should be directly involved in holding the ring between public and private needs. The Sanford committee rightly draws attention to the analogy between vaccine programmes and the arrangement for the insurance of nuclear power stations by the Price-Anderson Act, where the same principles are (or were once thought to be) at stake. The need now is that the US Congress should buckle down to the legislation it must know it cannot put off much longer. □

Growing charitable

Charitable foundations in the United States and Europe are learning how to flex their muscles.

EARLIER this year, the Howard Hughes Foundation leapfrogged its way to the top of the donors' league in the United States by divesting itself of TWA, the airline that was its founder's chief legacy. In due course, the result will no doubt make the foundation a force to be reckoned with in biomedical research. Although the charity's annual income will be less by more than an order of magnitude than that of the US National Institutes of Health (NIH), it will have the advantage of being uncommitted to the standing army of in-house researchers that NIH maintain and free from obligations wished on it by the US Congress. And now, independently and more cautiously, the Wellcome Trust in Britain proposes to take a leaf out of the Howard Hughes book. The two charities resemble each other in that their chief asset has from the beginning been the sole ownership of a commercial company, in Wellcome's case the drug house called confusingly the Wellcome Foundation. Next year, the trust plans to sell a fifth of its shareholding in the company, calculating that it will as a consequence be able to increase its spending on biomedical research by something like a factor of two. Already, the trust's grant-making, planned at £30 million during the year ahead exceeds what the British Medical Research Council can afford by way of research grants.

But why stop at the disposal of a mere fifth of the shareholding? Why not sell the lot, as the Howard Hughes Foundation sold the whole of the airline that was its birthright? The reason why it is financially advantageous for foundations to dispose of assets that consist of single companies is that, even when the companies are successful, they will sacrifice income (and their charitable objectives) for the chance of capital growth. But on the principle that there is no such thing as a free lunch, capital growth is not cast-iron. Even successful companies risk falling on hard times, as the Nuffield Foundation, once Britain's biggest, learned to its cost when, having sold a third of its shares in the British Motor Corporation, it found the rest bought by the British government at a knockdown price. Wellcome should sell more soon. □

Supercomputers

US seeks restrictions on foreign access

Washington

THE United States is pressing allied governments to restrict access to supercomputers by Soviet bloc nationals. Defense Department officials fear that access to the latest generation of machines could allow the Soviet Union to make significant advances in supercomputer technology and programming, or even to run programmes with military applications.

The new generation of supercomputers, exemplified by the Cray 2 or the Cyber 205 models, works at speeds in the gigaflop range, of the order of 10^9 floating point operations per second. The Soviet Union has no machines capable of this speed, which are made exclusively in the United States and Japan. Some employ innovative "vectorizing" software that allows limited parallel processing; and they can be used to test experimental parallel processing software that will lead to yet further advances in computing speeds.

Restrictions on access are likely to be no more popular with foreign than with US academics however. An acrimonious public dispute erupted last month because the National Science Foundation (NSF) asked several universities hosting NSF-financed "supercomputer centers" to ensure that citizens of COCOM-proscribed countries are denied access.

Only the centre at the University of California at San Diego agreed and, even there, officials say the matter has not been laid to rest. (The contract was actually signed by an industrial representative, and officials hint that things might have been different if the university had known more in time.) The centre at Princeton University made a curious compromise by volunteering to impose restrictions but only if required to do so by law, and two of the centres, at Cornell and Illinois, refused. NSF backed down, and officials now acknowledge that to impose restrictions without a national policy on access was "a mistake".

An attempt is being made to resolve the issue by an interagency group under the National Security Council; officials say that the academics will be heard, but at least one, Don Goldstein of the Department of Defense, contends that controls of some type will be necessary and that they should be in place within weeks. If no agreement is reached with universities, control might be achieved by denying entry visas to nationals of some countries planning to work on US supercomputers.

The Soviet Union is seen as the main threat, but there is also some concern about China, according to Goldstein. And he points out that it would be pointless to

impose controls on access in the United States while allowing unrestricted access to similar machines overseas.

Although supercomputers, running up to one hundred times faster than previous top-of-the-line models, can make otherwise daunting problems feasible, officials

Space cooperation

Summit speeds US/Soviet goals

Washington

No firm evidence has yet emerged of a decision by the US administration to pursue formal cooperation in space with the Soviets, despite a flurry of recent interest and the efforts of several US Senators who want President Reagan to make new proposals at his November summit with Soviet leader Mikhail Gorbachev. At recent hearings in Congress, a State Department official spoke of the desirability of renewed cooperation "down the road" but avoided making a commitment to renewing the agreement on cooperation in space that was allowed to lapse following the imposition of martial law in Poland.

At present there are a number of low-level contacts and exchanges between US and Soviet space scientists. Some US instruments are being flown on the Soviet Vega missions to comet Halley, for example, as they were on some of the Soviet Cosmos series of biosatellites. But there are no formal collaborations between the two countries directly, despite last year's Joint Resolution of Congress, signed by the President, committing the administration to work towards increased cooperation. A proposal last year by President Reagan for a joint simulated space rescue has remained unanswered.

Many believe there will be no significant upswing in cooperation with the Soviets until there is a new agreement; Soviet scientists do not have the same degree of latitude to "freelance" on joint projects as their counterparts in the United States. The earlier space cooperation agreement arose at the Nixon/Brezhnev summit in Moscow in 1972, which may thus be a precedent for next November.

The case for a joint Mars project is being pushed most notably by the Planetary Society, which together with the American Institute of Aeronautics and Astronautics held a meeting here last month to celebrate the tenth anniversary of the Apollo-Soyuz test project. The meeting was attended by Soviet cosmonauts who participated in the project, as well as by officials of the US National Aeronautics and Space Administration

admit it is unlikely that long-running programmes for submarine tracking or weapons design could be run clandestinely at a supercomputer centre.

Nevertheless, they say, the damage would be high should anyone succeed. And to be consistent, there will have to be restrictions on access to private supercomputers similar to those being talked about for academic institutions. Most of the world's 140-odd supercomputers are in the United States, and at present there seem to be no regulations limiting access to those owned by, for example, computer services companies. **Tim Beardsley**

(NASA). Significantly, NASA's administrator, James Beggs, gave his blessing to the idea of a manned Mars mission as a long-term goal.

The technical obstacles facing a manned Mars mission are indeed formidable, and NASA officials are quick to point out that there are no immediate plans for such an ambitious undertaking. More modest cooperation with the Soviets is thought more likely. NASA officials note approvingly that visiting Soviet scientists have recently been much more open about future Soviet space missions, and Dr Frank McDonald, NASA's chief scientist, expects attempts to coordinate with the Soviets over unmanned Mars missions planned for the end of the 1980s.

The Soviets have volunteered many details of their planned 1988 mission to the Mars moon Phobos, for example, and McDonald thinks there would be clear advantages to both sides in designing complementary instrumentation and if data were shared with a US Mars observer mission planned for 1990. A group of senators led by Spark Matsunaga has urged President Reagan, in legislation now pending, to raise the question of cooperation on Mars exploration with Gorbachev in November.

Congressional supporters of increased cooperation have recently been given some new ammunition in the form of a technical memorandum from the Office of Technology Assessment*. The memorandum notes several areas where cooperation with the Soviets has yielded technical benefits in the past, particularly the effects of long-duration space flight on astronauts and data about the surface of Venus. Despite American concerns about technology transfer, the memorandum concludes that there is potential for future cooperation on "global habitability", exobiology, Antarctic meteorites and some areas of astrophysics, as well as planetary exploration. **Tim Beardsley**

AIDS

Two British blood tests launched

THE first stage of the British government's evaluation of commercially available kits to screen blood for the AIDS (acquired immune deficiency syndrome) virus, HTLV-III (human T-cell lymphotropic virus), was completed last week. The Virus Reference Laboratory of the Public Health Service has tested five manufacturers' kits (Abbott Laboratories Ltd, Electronucleonics Ltd, Organon Teknika Ltd, Ortho Diagnostic Systems and Wellcome Diagnostics). Three performed appreciably better than the others in distinguishing clearly between negative, positive, false-positive and heat-treated sera. Two of these, from Wellcome (Britain) and Organon (the Netherlands), were found to be especially easy to use and are now to be tested by the Blood Transfusion Service on about 6,000 samples. When this evaluation is complete, routine screening of blood donations will be introduced, probably by mid-September.

Screening will protect those most vulnerable to the AIDS virus, that is, people dependent on blood transfusions. For the present, "at risk" individuals have been asked not to donate blood. But AIDS is unlikely to stay contained within some sections of the population. Already there are reports of the presence of antibodies to the virus in women in some African cities, confirming that the disease can be transmitted by heterosexual contact.

Although the kits will greatly increase the efficiency of detecting the AIDS virus in sera, and hence containing its spread, a cure for the disease is no closer, although recent results indicate that the drug Zidovudine can help patients with AIDS-related complex or lymphadenopathy syndrome.

The AIDS virus replicates within the body's immune system and, although it is highly infectious, only 3 per cent of people infected with HTLV-III develop AIDS; however, another 20 per cent develop illnesses of varying severity ranging up to persistent generalized lymphadenopathy.

AIDS is almost always fatal, but the virus has a long incubation time. In July 1985, about 10,000 people in the United Kingdom and a million in the United States were estimated to be infected with HTLV-III. Until treatment is available, the first step in management of the condition is to prevent the spread of infection by screening blood for HTLV-III antibodies. The kits evaluated last week accurately identify the presence of HTLV-III antibodies in the blood. The next development will be to develop a test for the antigen, which will allow earlier identification of the virus, before an individual has made antibodies. It is hoped that antigen tests will be easier to perform and more sensitive than antibody binding.

Of the tests chosen for further evaluation in Britain, Wellcome's is a competi-

tive enzyme-linked immunosorbent assay (ELISA) and Organon's, in common with the unsuccessful tests, is an indirect ELISA. The Wellcome kit consists of a plastic well first coated with "control" HTLV-III antibody and then with impure HTLV-III antigen. (This procedure purifies the antigen.) The user adds to the well a test sample of serum together with a conjugate of control antibody linked to the enzyme horseradish peroxidase. HTLV-III antibodies in the sample compete with the enzyme-linked antibody in binding to the antigen. Unbound components of the mixture are washed out, and the substrate of the enzyme added to the wells. Any enzyme still bound to the wells is seen as a blue colour, and when the reaction is stopped with sulphuric acid, a yellow colour develops. If antibodies were present in the sample, some will have bound to the antigen; because they are not enzyme-linked, less colour develops.

The indirect ELISA also starts with antibody-antigen-coated wells. The sample is then added, washed, then enzyme-linked human anti-immunoglobulin G (IgG) is added to the mixture. Any antibody in the sample will bind to the anti-IgG and the development of colour indicates HTLV-III antibodies are present.

In both tests, samples scoring positive are subjected to a confirmatory test, such as Western blotting, in which the constituent proteins of the virus are separated on a two-dimensional gel and identified by their relative molecular mass.

The Wellcome test may have an advantage over the indirect ELISA because there are fewer steps (five against Organon's eight and taking two hours rather than just under three), there is not as much sample dilution and it is potentially more specific as it uses the principle of competition rather than binding to a more general antibody. However, the National Institute of Biological Standards and Control has found no difference in specificity between the two successful tests on a limited number of samples. **Maxine Clarke**

AIDS

US blood-bank tests established

Washington

SECOND-generation tests for the AIDS (acquired immune deficiency syndrome) virus that may reduce the persistent problem of false positives have produced encouraging early results. Abbott Laboratories, Centocor and Travenol-Genentech are among US companies evaluating enzyme-linked immunosorbent assay (ELISA) tests that incorporate recombinant antigen, which avoids at least some of the problems caused by the natural variability of the virus.

Some preliminary data on the new tests were given last week at a government-sponsored conference at the National Institutes of Health. In addition, Abbott claims to have a prototype test that detects viral antigens in the blood, as distinct from the human antibodies that existing ELISA tests look for. A workable antigen test would be a much surer guide to those at risk of developing the disease or to carriers of the disease; it is, however, technically more demanding because antigens are present in much lower concentrations than antibodies.

The existing licensed tests on the UK market, supplied by Abbott, Electronucleonics and Litton, are generally agreed to have effectively protected blood banks; virtually all blood samples from AIDS patients are detected. But there remains a substantial number of repeatedly reactive samples that do not show evidence of antibodies on a Western blot test, even when technical errors are excluded.

In Western blotting, the principle of the better-known Southern and Northern blotting techniques is extended to the de-

tection of proteins rather than nucleic acid fragments. The protein mixture for assay is size fractionated by gel electrophoresis, followed by transfer to a support in such a way as to preserve the relative positions of the separated proteins. Specific proteins attached to the support can then be detected with antibodies.

The Western blot is considered more reliable than ELISA testing, although even so it shows appreciable variation between laboratories, according to Carl Saxinger of the National Cancer Institute. One reason for the large number of false positives is mutation in the virus populations that supply the antigens used in tests. Recombinant antigens would be more stable (although the problem of sample virus variability would remain) and so perhaps reduce the false-positive rate. A cocktail of different recombinant antigens might be the best solution. Recombinant antigens have the additional advantage of avoiding the need to culture live virus.

The false-positive problem has led to harrowing decisions about what to tell patients whose samples appear positive, although manufacturers stress that current tests are not intended for use in diagnosis. The presence of antibodies, even if confirmed, does not necessarily imply that overt disease will develop. Looking to the future, some manufacturers expect to be producing batteries of confirmatory tests for antibodies characteristic of different stages of infection and disease. Together with a viral antigen test, these may allow immune people to be recognized and thus provide useful data on the progress of infection. **Tim Beardsley**

British forests

Tax breaks for broadleaved trees

MULTIPURPOSE use is an increasingly popular catchword among natural resource managers, implying that seemingly conflicting demands on a resource, such as a trout stream and a hydropower dam, can in reality be harmonized. The concept is the lynchpin of the British Forestry Commission's (FC) new broadleaved woodlands policy, intended to give enough tax relief and grant aid to make growing broadleaved trees profitable. These incentives, according to the commission, will persuade landowners voluntarily to manage now-neglected broadleaved woodlands and also to plant new stands, thus providing a habitat for native British wildlife and soothing the British eye for beauty, which prefers a native oak to an exotic conifer.

The principal criticism of the new programme, from foresters and conservation groups alike, is that broadleaves are hard to grow and that the commission's system of advisers for helping landowners will be understaffed and underbudgeted. The commission, on the other hand, claims the government is committed to the advisory system and will review it in 3–5 years.

One-third of Britain's productive timberland (566,000 hectares) is planted in broadleaves, with virtually all of that in the lowlands and in private hands. Broadleaves management, therefore, is clearly a question of motivating the private sector. Neither broadleaves nor conifers are self-supporting timber industries, according to Mr David Conder of the Council for the Protection of Rural England; therefore, broadleaves, for which there is "an environmental and recreational preference", should be given the more attractive tax break.

Conifers and broadleaves, however, are more dissimilar than Mr Conder suggests: the latter grow more slowly, need more room and produce less usable timber. Mr Esmond Harris of the Royal Forestry Society of England and Wales claims, for example, that Corsican pine stands in the Forest of Dean are three to four times more valuable than the broadleaves grown there.

Private landowners would like to see a profit within their own lifetime, so research by the Forestry Commission and private interests into higher-quality and faster-growing broadleaves is as important as new tax and grant schemes. Mr Harris points to plastic tubes that shelter young broadleaves, helping them grow four times faster than by conventional methods and halving the 120–150 years many broadleaves need to mature. Making broadleaves a commercial success, says Mr Harris, is the key for conservation efforts: wildlife needs can then be incorporated into productive woodlands rather than forcing land to be set aside just

for habitat.

Part of the growing public interest in broadleaves is a backlash against conifers, which it is claimed do not support ancient woodland plants, create acidity on the soil's surface and leach nutrients from the soil. Mr Mark Anderson, forest ecologist at the commission, says conifers do not deserve such blackballing. He points to the cycle of canopy closure and species differences in litter properties — whether the leaves pack down and rot or not — as the crucial elements in plant colonization. Conifers do acidify surface soil, particularly in the uplands where the soil has little buffering capacity, but these properties peak and trough and then revert to approximately their initial values by the end of the rotation. And finally, tannin does

wash out of conifer leaves, chemically associate with soil nutrients and wash to lower levels; but this behaviour happens primarily in poor soil and is also associated with broadleaves.

The upland conifer issue, according to Mr John Andrews of the Royal Society for the Protection of Birds, comes down to a conflict between agriculture and forestry. As agriculture has been allowed more hill land, forest plantations have been pushed further north and west into poorer and poorer land that is also valuable bird habitat. There the trees do not grow large and are subject to considerable windfall, which means there are no old trees for birds to drill holes in. By "moving the centre of gravity of forestry downhill", says Mr Andrews, the Forestry Commission could grow better trees while leaving the windswept moors with the poorest soils to the birds and animals that do in fact thrive there.

Elizabeth Collins

Deep-sea clams

New find near Japan's coast

Tokyo

GIANT clam colonies, first reported from the deep sea off Japan only two months ago (*Nature* 315, 624; 1985) are now popping up right, left and centre, from as little as a kilometre off the Izu Peninsula to a depth of over 5,000 metres in the Japan Trench. Discovery of the colonies provides a golden opportunity to study these strange organisms, believed to draw their energy from a source in the Earth beneath them rather than the Sun above.

Days after the French submersible *Nautille* located giant clam colonies at a record depth of 3,840 m in the mouth of the Tenryu Canyon off the Pacific coast, Japan's submersible *Shinkai 2000* found similar colonies in Sagami Bay at a depth of 1,300 m, a mere stone's throw away from the hot spring resort town of Ito on the Izu Peninsula. A month later, *Nautille* shattered its own record with the discovery of another clam colony at 5,640 m on the steep inner wall of the Japan Trench, immediately opposite the First Kashima seamount.

This discovery was made by Kantaro Fujioka of the Ocean Research Institute, University of Tokyo, during the second leg of the Franco-Japanese project Kaiko, led jointly by Guy Pautot of IFREMER and Kazuaki Nakamura of the Earthquake Research Centre, University of Tokyo. The colony, measuring two by one metres, consists of banana-shaped clams up to about 15 cm in length which have tentatively been identified as *Calyptogena* sp.; they are stacked together forming an imbrication parallel to the long axis of the colony.

As in the case of the Tenryu Canyon colonies, a positive temperature anomaly of about 0.3°C was associated with the colony which occurred in a slight depress-

ion. There are reports that the French have found an even deeper colony during the third and final leg of Kaiko now in progress at the northern end of the Japan Trench.

The colonies off the Izu Peninsula are larger, the biggest living colony being twenty by five metres, and, like the Tenryu Canyon and Japan Trench colonies, are associated with thrust faulting caused by subduction as the Izu Peninsula riding on the Philippine plate ploughs into the rest of Japan. Clams collected by Teruaki Ishi of the Ocean Research Institute have been identified as *Calyptogena soyoe* by Sugura Ohta of the same institute, who also recognized in video records what appear to be vestimentiferan tube worms attached to a ledge above the clam colony.

Unfortunately, *Shinkai 2000* was unable to collect specimens of the worms, which have not been found at the deeper colonies. Despite proximity to hot springs on land, Dr Ohta does not think the colonies off Izu derive their energy from hot vents as at mid-ocean spreading ridges but, rather, suspects that they are sustained by old seawater "squeezed" out along fault planes by subduction.

The find off Izu is well within the 2,000-m depth range of *Shinkai 2000* and lies very close to land, opening up the possibility of regular *in situ* experiments. A deeper-going Japanese submersible capable of examining the Japan Trench colonies is at the design stage. Although the new submersible was originally intended to have a depth limit of 6,000 metres as in the case of *Nautille*, an advisory body to the Science and Technology Agency recommended last month that this should be increased to 6,500 metres, thereby allowing access to all but the deepest trench basins off Japan.

David Swinbanks

US vaccination

Statutory compensation urged

Washington

THE Institute for Medicine last week added its voice to the many others complaining that present disincentives to the development and production of vaccines constitute a threat to public health in the United States. There is no knowing whether this latest warning will carry weight with the administration, the Congress and the courts.

Plaintively, the committee responsible for last week's report, *Vaccine supply and innovation*, remarks that recommendations of previous committees have been ignored "for reasons unrelated to the potential utility of the recommendations", which is a polite way of saying that political considerations and/or idleness have supervened.

The Institute of Medicine's committee, under its chairman Jay P. Sanford of the Uniformed Services University of the Health Sciences, argues that continuing immunization against an extended range of infections should be an essential part of public health provision in the United States. But the committee says that vaccine supply is made "precarious" by the obstacles faced by manufacturers, some of which are economic (attenuated patent protection, for example) and others legal, particularly the uncertainty about liability for injuries associated with the administration of vaccines.

The most arresting part of the commit-

tee's argument is its careful demonstration that the application of the present law is shot through with anomalies. Its chief recommendations are that there should be a national vaccine commission in the United States to anticipate problems connected with vaccination, together with a statutory compensation scheme.

Paediatric vaccines are the most immediate worry, according to the committee, which says that two of the three manufacturers of DTP vaccine (offering protection against diphtheria, tetanus and pertussis or whooping-cough infections) had given up manufacture of the vaccine a year ago. Since then, apparently, Wyeth has subcontracted to supply Lederle with vaccine not for distribution under its own label, while Connaught Laboratories (a subsidiary of Squibb) has managed to obtain liability insurance to allow manufacture to be resumed.

There are similar problems with the supply of poliomyelitis and the combined measles, mumps and rubella (german measles) vaccines, with stockpiles held by the Centers for Disease Control down to 15 and 12 weeks respectively, partly because of congressional niggardliness on the cost of the stockpile programme. The committee says that the supply position is "disconcertingly unstable".

On the economic front, the committee says that part of the reason for the twofold reduction of the number of manufacturers

making vaccines between 1968 and 1975 may be that the vaccine business is less profitable than the development of pharmaceuticals. The cost of developing new vaccines is estimated at between \$20 million and \$30 million, shared roughly equally between manufacturers (who pay for clinical trials and production development) and the federal agencies, which bear the cost of basic research.

The total value of the vaccine market in 1982, on the other hand, is estimated to have been \$170 million, which the committee says may be only a fraction of the sales in a single year of a successful drug. Even so, according to the committee, the economic basis of the vaccine industry may recently have been strengthened by last year's legislation extending the patent life of new medicines to compensate for licensing delays, the decision of the Supreme Court in 1980 that strains of living organisms may be patented and administrative decisions during the past few years that have given universities and other recipients of federal grants the right (and even the responsibility) to exploit intellectual property arising from their research.

On the legal front, the committee is less optimistic. A survey among manufacturers in the spring last year showed that there were 166 outstanding liability suits, and a further 65 were laid in the following twelve months. Only a small proportion of the outstanding claims had been settled in the interval, often for amounts of the order of \$1 million. Some manufacturers claimed that legal costs of defending vaccine suits amounted to "several millions of dollars a year" and that the cost of defending a single suit might amount to \$500,000.

Citing the law as it stands, the committee says that a manufacturer cannot be held responsible for damage done by a vaccine which is not defective, but goes on to complain that courts in various of the United States have been prone to interpret the legal position more broadly, and in unpredictable ways.

In legal suits during the past fifteen years, it seems that a manufacturer's duty to warn recipients of a vaccine (or, when children, their parents) of the dangers of vaccination has commonly contributed to the award of damages against manufacturers. The committee cites one suit in which the manufacturer was held liable for the occurrence of polio in the parent of a child vaccinated with Sabin (attenuated live virus) vaccine and administered by the Texas Department of Public Health. The courts held that the parent should have been told that the prior administration of Salk vaccine would have avoided the risk; the Institute of Medicine's committee points out that Salk vaccine was not being manufactured at the time.

In another case, a manufacturer was found to be liable for damage caused by Sabin vaccine because the physician who had administered it privately felt that the warning on the package insert that a few

A check-list of vaccine hazards

THE Institute of Medicine report says that attempts to measure the risks associated with vaccines are complicated by the difficulty of relating cause and effect, by the circumstances that vaccine injury tends to be regarded seriously only after the incidence of damage from the uncontrolled infection has been substantially reduced and because of the lack of knowledge of the mechanism of vaccine injury. But immunodeficiency argues against the use of vaccines of any kind.

On the basis of experience in the United States, the report gives the following data. Pertussis. The frequency of fever (39°C or more) is roughly 7 per cent within 24 hours of vaccination, apparently a consequence of the pertussis component of DTP (diphtheria-tetanus-pertussis) vaccine. The frequency of permanent injury, in the form of encephalopathy, is reckoned, from British data, to be one in about 150,000 in infants given three doses in the first year of life.

Diphtheria. While earlier preparations of the toxin produced temporary reactions, better purification has eliminated fatal or disabling reactions.

Tetanus. Anaphylactic reactions to tetanus

toxin are recognized at the rate of 1 per 1.5 to 2.0 million doses, but no fatalities are known.

Poliomyelitis. The risk of contracting paralytic polio from its oral vaccine is estimated at 1 in 11 million doses. But the committee says that consideration is now being given to switching back to inactivated polio vaccine.

Measles. Between 5 and 15 per cent of infants at 15 months develop a fever of 39.4°C a week after vaccination. Measles encephalitis, a complication of the natural infection, is estimated permanently to affect fewer than 1 in a million vaccinated children. The rate of slow-virus infection, leading to progressive fatal neurological disease, is too small to be estimated.

Rubella. Persistent arthritic conditions are recognized in a few vaccinated women.

Mumps. The report recognizes no permanent consequences of the use of mumps vaccine except that of allergic reaction to proteins from the eggs in which the virus is grown.

Influenza. The 500 cases of Guillain-Barré syndrome reported after the use of swine flu vaccine in 1976 are "unprecedented"; the cause remains unknown. □

vaccinations in a million might lead to poliomyelitis infection was not sufficiently explicit to pass on to the parents of a vaccinated child. The committee says that "the sceptical reader" may fairly conclude that US courts behave as if "the manufacturer is responsible for all damages caused by a vaccine".

The great swine influenza fuss of 1976 is offered as a complicating precedent. Out of fear of a swine flu epidemic on the scale of the 1919 influenza epidemic, and in the face of manufacturers' unwillingness to produce vaccine in the time required without indemnity, the US Congress passed legislation placing liability for damage on the federal government, which was afterwards interpreted (by the then Secretary of the Department of Health Education and Welfare, Joseph A. Califano) to imply that strict liability for all injuries would rest against the United States.

In the event, the influenza epidemic did not materialize, but among those vaccinated, between 1 in 100,000 and 1 in 200,000 developed the neurological complications of the Guillain-Barré syndrome. The US government has already paid out \$73 million to claimants. Legal cases stemming from the episode have tended to be settled on the basis of strict liability.

The Sanford committee's proposal that there should be a permanent vaccine commission takes the somewhat unusual form of recommending that the commission should be set up, at a cost estimated at \$1 million a year, as a congressionally chartered body, reporting annually. But the committee says that other locations of the commission within the US government structure would be acceptable.

The committee argues that the case for compensating victims and their families stems from the fact that vaccination is sometimes compulsory (as for children entering the educational system) and that vaccination of an individual contributes to the public as well as the personal good.

On balance, the committee is for a system in which compensation would be paid from a fund recruited by a levy on vaccine sales. It emphasizes that such a scheme would not absolve manufacturers from the duty to avoid defects in their products.

The amount of compensation to be paid, the committee argues, should be devised so as to "restore the incentive to participate" in vaccination programmes, avoid financial devastation of victims' families, keep vaccine costs low, avoid disproportionate spending on a field of public health which is "important [but] not the only legitimate claim on . . . resources" and to remove the incentive to litigation.

The committee leaves to others the question of whether a compensation scheme should be accompanied by an extinction of people's right to sue under the law of tort, but instead offers a menu of ten alternative schemes from which readers may choose □

Australian space

Never too late to change

Canberra

WITH the launching of the first three domestic communications satellites of the Aussat-1 series later this month, the Australian government faces some difficult policy choices. The Minister for Communications, Mr Duffy, has warned that changes may be in the offing to regulations that have been on the books for 30 years. Deciding how the local broadcasting market is to be carved up between the large national networks and the smaller regional broadcasters is one problem; the provision of telephone services to remote outback communities another. While Telecom, the government's monopoly carrier for public switched telecommunications, is protected in its role by the Satellite Communications Act 1984, Aussat will compete in the areas of private leased networks, data communications and in other fields. For Australia's space-related industries, however, the big question is whether the government will assist them in rekindling an earlier vigour which petered out when ELDO (European Launcher Development Organization, of which Australia was the launch-site member) gave way to ESA, the European Space Agency, leaving the locals without a space policy coordinating body.

At a time when national communications satellites are going aloft all round the world, Australia's share in the manufacture of space systems has dwindled to the point where the weather map appearing nightly on Australian television screens is beamed down from Japan's GMS-3 meteorological satellite and people are beginning to wonder whether the governments of countries with more sophisticated space technologies know more about Australia's natural resources than do Australians.

Whether all this changes will depend to a great extent on the government's response to the recommendations of the Madigan report — a space policy for Australia published by the Australian Academy of Technological Sciences which asserts that Australia still possesses the technological and industrial ability to develop an effective space programme, but that the actors will need to be welded together by prompt government action in the formation of a space technology and research authority.

Furthermore, the government will have to invest about \$A100 million over the next five years in order to stimulate academic space research and to put Australian companies in a position to bid for international contracts by first weaning them on national research and development projects.

The Madigan report also recommended that the Australian Landsat facilities be

upgraded, and identified equipment for ground receiving stations and the remote sensing of Earth resources as immediate priorities for Australian industry.

The Commonwealth Scientific and Industrial Research Organisation (CSIRO) was quick off the mark. Having both established a space science study group and designated space as one of its principal growth areas, CSIRO set up a body to coordinate the organization's efforts in the field, called the CSIRO Office for Space Science and Applications (COSSA). It is headed by Dr Ken McCracken, formerly chief of the CSIRO division of mineral physics.

As soon as the Madigan report was published, COSSA put forward a detailed proposal of the steps that would be needed if Australian industry was to reach the point where it could gain the prime contracts for Aussat-3, due to be built in 1994.

Two current projects were pointed out as good examples of the kind of work which would qualify Australia as a contractor: the scanning infrared radiometer developed at the CSIRO division of atmospheric research (capable of detecting 0.3° temperature changes in the surface of the sea) and the large-format detector of the Mt Stromlo-based Australian part of the FUSE/Lyman (far ultraviolet space explorer) satellite.

But the timing is crucial. COSSA estimates that local industry may have gained sufficient experience in spacecraft design to play a considerable part in the design phase of Aussat-2. But the same cannot be said for the 1989 construction phase. The bridging of this "experience gap", COSSA suggests, should be Australia's participation in the refurbishing of the US Spartan reusable spacecraft and the construction of the scientific instrument package to fly on it.

The resulting satellite — to be launched in 1988 and called Mirrabooka, an aboriginal word for the Southern Cross — will be a fast-turn-around vehicle for further experiments and, if all goes well, may qualify Australian contractors for about 30 per cent of the space acquisitions of Aussat-2, due for launching in 1992.

The government has already taken notice. Last week, the Minister for Industry, Technology and Commerce, Senator John Button, announced the award of a \$A3 million contract for three 18-m Earth stations for international television transmission of the America's Cup defence, a \$A2.5 million contract to develop rooftop Earth stations for the Intelsat business services network and a \$A18 million contract to build seven 22-m antennas at Culgoora and Siding Spring for the Australia Telescope (see *Nature* 311, 500, 1984).
Jeffrey Sellar

Whaling

Inaccuracies in numbers

THE difficulty of counting whales accurately has muddled the already turbulent management task of the International Whaling Commission (IWC), whose recent meeting in Bournemouth, Dorset, was the last before a ten-year moratorium on commercial whaling is due to take effect in 1986. The Scientific Committee of IWC will spend that decade on a specific task: researching ways of counting whales and analysing how to incorporate these numbers and their uncertainties into the

management procedure.

Counting whales is not as easy as counting trees or fish. Scientists are confident that the computer models and counting methods used to extrapolate population size and growth trends for trees or fish are accurate — or at least accurate enough to manage the resource. Trees have the comforting habit of standing still, and we know the biology and reproductive rates of fish well enough to predict trends. There is increasing recognition, however, that similar methods applied to whales result in confidence limits so wide that only an extreme change in numbers will register.

Whaling data have traditionally been garnered from the whaling industry itself. A common method has been that of "catch per unit effort", which derived from fisheries work. An index is established from the size of the catch and the amount of effort involved: in other words, if the same effort is involved and a catch is half its former size, the population is half its former size. Sidney Holt, a fisheries biologist now acting as a consultant on marine affairs, is one of many scientists who point to the difficulty of quantifying "effort" and the nonlinear relationship of the index to the actual population size.

Another option is to mark and recapture. Whales are either marked artificially or recognized by their natural marks. If 100 whales are marked or recognized and the next year five of them are recognized again or caught by whalers, the actual population is approximately 20×100 in size. Individual humpback and right whales, according to Dr Lex Hiby of the Sea Mammal Research Unit, which is supported by the Natural Environment Research Council, are easy to recognize and

blue whales are potentially so because of a lacy pattern on their skin; these species, however, have already been decimated to the point of being protected species. And IWC is having to recognize that artificial marks do not work well for the commercially viable minke and sperm whales. The metal bolts used can kill the whales as they are marked, there is no way to know if a bolt has actually lodged in a whale, and it is now being shown that the bolts are sometimes extruded.

The sightings method, criss-crossing a given area by plane or ship and estimating the density of whales, is now recognized as offering the best possibilities for an accurate counting model. As at present used, the confidence limits of this method are very wide, says Holt — so wide that a population could be a third of its original size before the change was recognized. The problem is that the method is based on one developed for tree research, which assumes that if a tree is right on the observer's path, it will be seen. Whales, however, dive and travel towards and away from the observer, which means there is no assurance that whales right on the path will be counted accurately. The Sea Mammal Research Unit is part of an international effort to control variability

in sightings counts, running such experiments in the Antarctic as counting whales from ships moving in parallel or counting whale blows per unit area per unit time.

The scientific committee's review of the data gathered during the moratorium, as well as of research priorities and survey methods, is intended to establish more accurate guidelines for gauging the impact of whaling. If the effort fails, says Dr John Harwood, head of the Sea Mammal Research Unit, it will be a "sad reflection on science and management". It will also in part determine whether Mr John MacGregor, Minister of Agriculture, Fisheries and Food, was right in calling the moratorium "a landmark in the long history of man's relationship with these most fascinating creatures of the sea".

But whether there really will be a lapse in commercial whaling depends on such factors as US pressure on Japan and whether South Korea and Iceland do in fact kill over 200 whales each year for "scientific research". Even if IWC had real teeth and enough money, the world's oceans are such a huge area to monitor that the success of the moratorium is dependent on the cooperation of the countries that have the most to gain by ignoring it. Luckily some species of whale, notably the blue, will receive added protection under an international convention to protect threatened migratory animals, which Britain signed last week. **Elizabeth Collins**

French research

Southern festival of science

WHY not take in a laboratory or two on the way south to the Côte d'Azur? Until 18 August, the leading French research council (the Centre National de la Recherche Scientifique) is running a kind of continuous science festival at three of its laboratories in the south of France. The project is the successor to a major CNRS achievement last year, when it took over 2,000 square metres of space under the Eiffel Tower in Paris for 2 weeks for an exhibition on all aspects of communication, from technology to languages and involving journalists, actors and a variety of forms of presentation. Some 10,000 visitors attended, and M. Goéry Delacotte, CNRS director of information, is hoping for a similar success in the south.

"People are always asking us what we have discovered with their money", says Delacotte, and with these exhibitions CNRS is setting out to reply — and, no doubt, to win friends and influence people. It has set up a full-time "exploration workshop" in Meudon, near Paris, with a model-making staff of 10. Some of the results are in use at the new festival in the south.

Delacotte is particularly proud of a lens designed to show the precise gravitational lensing of a quasar by a nearby galaxy, separating the quasar light into three

different images. That is on display at the 13-telescope Observatoire de Haute Provence, near St Michel. Also on show are atmospheric studies by LIDAR, work in interacting galaxies (the Magellanic Clouds) and studies of Halley's comet (in which the observatory is closely involved), all with mock-ups and exhibits.

Other sites involved are the solar energy laboratory at Odeilla-Font-Romeu (in the east Pyrenees) and a group of marine laboratories at Villefranche-sur-mer. At all these exhibition sites there are regular lectures, exhibitions and activities for children.

What is more, visitors will also find real scientists of whom to ask questions, it now being an official duty of a French scientist, and one which can in principle advance his or her career, to popularize science.

CNRS is spending some FF 2 million (£160,000) per site for the festival, Delacotte estimates. If this year's trial is successful, the exercise may spread to cover the whole of France. "It's important to reach a critical mass", Delacotte says.

Nuclear winter

Canadian forest burn as model

Washington

US and Canadian scientists flew to northern Ontario last weekend to watch what happens when 6 square kilometres of dry forest is doused with a petroleum mixture and set alight. Their aim was to see whether measurements from such planned fires could help to decide how likely it is that a nuclear war would give rise to "nuclear winter" — a global lowering of temperature caused by soot in the atmosphere. But the fire has already caused some unplanned political fallout.

The forest, 25 kilometres north-west of Chapleau, was infested with spruce budworm and was due to have been burned anyway — the Ontario Ministry of Natural Resources organizes about 50 such "prescribed burns" every year. This one, according to Bob Thomas of the Aviation

and Fire Management Center in Sault Ste Marie, was no different from any other, though it was one of the larger ones. The forest, which had been bulldozed flat, was ignited from several points by helicopters flying in spirals, drenching the wood with a thickened petroleum compound much like napalm. This ignition technique, developed only last year, means that a forest can be burned very quickly.

Mike Frankel of the US Defense Nuclear Agency said last week that the purpose of the visit was simply to see whether the fire would be a true mass fire of the sort produced by nuclear explosions, as distinct from one composed of moving fronts, like a natural forest fire. If the fire were sufficiently intense, the trip might lead to a formal collaboration with the Canadians, with detailed observations of future prescribed burns from aircraft.

Although burning wood produces much less sooty smoke than would a burning city, and is therefore less likely to have climatic effects, there is still much that can be learned from studying mass forest fires, according to Frankel: the relation between energy release rates and the height of the convective column, the fate of entrained water vapour and the optical properties of the smoke plume as it is dispersed are all effects that cannot be predicted with confidence by extrapolating from small fires.

Canada has no formal nuclear winter research programme, although a report earlier this year from the Canadian Royal Society recommended that Canada should contribute to studies of this phenomenon. The idea of studying prescribed burns arose out of conversations between Frankel, George Carrier of Harvard University, who chaired the US National Academy of Sciences study of nuclear winter, and Brian Stocks of the Canadian Forestry Service. The fire was also watched by university researchers and by representatives of Environment Canada and the Canadian Department of National Defence; from the United States came observers from the Defense Nuclear Agency, TRW Inc. and Los Alamos National Laboratory. Any future collaboration would involve, on the US side, the Defense Nuclear Agency, which is (together with Lawrence Livermore National Laboratory) the main agency studying nuclear winter; the total US nuclear winter budget is put at \$5.5 million.

Nuclear weapons are a politically touchy issue in Canada and politics might limit the extent of future work. Although last weekend's observation was originally to have been an informal affair, indignant local press coverage obliged the Canadian authorities to be seen to be in charge, which they did by placing a limit on the number of observers.

Athletic doping

Hungarian owns up

A HUNGARIAN pharmacologist, Dr Zoltan Torma, has admitted administering banned drugs and anabolic steroids to Hungarian athletes, the first time that such an admission has been made in the socialist bloc. Writing in the Budapest literary weekly, *Elet és Irodalom*, Dr Torma, who is employed at the National Physical Education and Sports Centre in Budapest, justified his actions by claiming that, left to themselves, the athletes would endanger their health by taking arbitrary doses. A qualified practitioner, he said, can at least administer the minimum necessary.

Dr Torma's article has sparked off an extensive discussion in the media on doping. Hungary's National Sports Office has in recent years spent the equivalent of US\$250,000 on anti-doping measures, but there seems to be tacit acceptance among Hungarian athletes and sports coaches that, without doping, Hungarian athletes cannot hope to compete internationally against competitors who resort to unauthorized use of drugs.

Dr Torma's excuse is not new. It was offered, for example, some years ago in the United States, in defence of allegations of doping in the case of the San Diego Chargers. What is significant, however, is that even the chief doctor of the Sports Office, Dr Istvan Kojtar, openly admitted, in an article in the sporting daily *Nepsport*, that it is virtually impossible to stop an athlete taking drugs if he is really set on doing so, and that doctors who refuse their assistance know that athletes risk severe damage to their health by self-administration. He suggested, however, that there should be a greater "social investigation" into the use of drugs in sport that would place it within the context of other social problems such as "non-sporting" drug abuse.

Dr Torma clearly agrees. He called for a clean up of Hungarian domestic sport, in which officials, coaches and athletes would be obliged to take a clear-cut stance against doping and the misuse of anabolic steroids. This, if Hungarian athletes' suspicions of their international competitors are correct, could considerably weaken Hungary's chances in international competition for some years.

The answer, clearly, is better doping control at the international level. Dr Torma himself would like to see a situation in which the International Olympic Committee would have the right to enforce random doping tests on any of its members at any time, so that athletes could be checked during training, and not just, as at present, immediately before a competition. However, not all members of the committee support this idea.

Vera Rich

Aleksandrov still not found

THE fate of Dr Vladimir Aleksandrov, the Soviet expert on nuclear winter who disappeared from an international meeting in Spain last March (see *Nature* 4 July, p.3), continues to cause concern to his colleagues abroad. Requests for information to Soviet colleagues have evoked only noncommittal responses such as "It was a tragedy, but we do not have many details". Some Soviet scientists have stated that their government has made requests for information through "diplomatic and other channels", but without success. According to one source, the Soviet government has also asked the International Committee for the Red Cross (IRC) to trace Aleksandrov, but Pascal Gondrand, spokesman of the IRC information department in Geneva, has no knowledge of any such request.

Although it has still not proved possible to establish Aleksandrov's movements immediately before his disappearance, details of his family situation received in the past month suggest that it is extremely unlikely that he disappeared voluntarily. He was known to be seriously concerned about his wife's health, and had sought the help of a London specialist, to whom he had sent, through a colleague, the results of a liver biopsy on Mrs Aleksandrova, carried out in the Soviet Union. The specialist had replied that it was impossible to complete a diagnosis solely on the basis of the materials so far supplied. Aleksandrov, however, was due to take part in a meeting of the ENUWAR (Environmental Consequences of Nuclear War) study group at the University of Essex in June, and (until he vanished) it was understood that he would take advantage of the meeting in England to deliver further diagnostic material to the London consultant.

Vera Rich

The meaning of "human life"

SIR—In the context of the recent, abortive Unborn Children (Protection) Bill in the UK House of Commons, opinions were voiced about the propriety or otherwise of conducting experiments on human embryos which were "alive"; but I am aware of no serious attempts by biologists to clarify the issue by providing an authoritative definition of what constitutes human life observationally.

Since this issue is likely to recur, I should like to summarize the meaning of (human) life as known from observation.

(1) The property of life, whether human or otherwise, is observably of two different qualities: namely, (a) dependently viable, protoplasmic life (at the level of scale of the molecule), and (b) independently viable, organismal life (at the level of scale of the individual), which in humans is also called "spirit".

(2) Dependently viable, protoplasmic life (1a above) — which, to the best of our knowledge, originated some 3,000 million years ago, and has continued (by means of repeated cell division) without interruption to the present day — characterizes the germ-lines of human beings: that is, the succession of gametes, both ova and sperm; which mediate human inheritance.

(3) Independently viable, organismal life or spirit (1b above) — which observably originates at viable birth, and continues without interruption until organismal death — characterizes the lives of human beings as individuals.

(4) It is thus not sufficient to refer simply to human "life". It is necessary to specify that particular quality of life to which reference is to be made: that is, whether to (a) continuous, protoplasmic life: which generally lingers in body tissues, even after organismal death, and which (as when a body is artificially ventilated) may continue so to linger indefinitely: or to (b) discontinuous, organismal life or spirit, which organismal death invariably displaces.

(5) How, then, shall we specify the quality of life in an embryo (or a fetus) *in utero*?

(6) That it possesses the quality of dependent, protoplasmic life (1a) follows from its observable intra-uterine growth (by cell division) and development (by cell differentiation).

(7) That it does not possess the quality of independent organismal life (1b) before viable birth, follows by definition.

(8) That it does not necessarily possess the quality of potential organismal life, follows from the finite probability of either unavoidable miscarriage or unavoidable still-birth (and, perhaps, as a never-viable monster).

(9) It follows that the life quality which is necessarily attributable to an embryo or fetus *in utero* is that of protoplasmic life: treated as an extension of the

protoplasmic life of its mother to which (for its supply of energy) it is dependently attached, and until such time as, by virtue of its viable birth, a protoplasmically alive fetus acquires the organismal quality of an independently alive human being.

(10) That is to say, human life passes through the following general cycle: (a) *In utero*, the embryo/fetus is alive protoplasmically, being dependent (for its energy) on its mother. (b) After viable birth, the human individual is alive both protoplasmically and organismally, being dependent (for its energy) only on itself — that is, it is independent. (c) After organismal ("brain") death, the body of the human individual remains alive protoplasmically, but no longer independently. Therefore, *unless* it be quickly provided with a surrogate mother in the form of an artificial ventilator, inevitably the organismally dead human being progresses also to protoplasmic death.

Down with metric

SIR—Your anonymous commentator (*Nature* 27 June, p.702) is both factually and conceptually incorrect. The first space shuttle laser-stabilization test did not fail because of confusion between nautical and statute miles. The ground-based laser was on a 10,023-foot high Hawaiian volcano. The on-board computer was given this height in feet rather than the nautical miles it was expecting. The volcano became in the computer's mind a 10,023-mile-high mountain. Since the peak would be above the shuttle, the on-board computer faithfully rolled the shuttle so that the mirrored side faced upward to receive the anticipated light-beam. When the on-board computer was later informed that the height was really in feet, the system worked perfectly.

Your commentator then runs on with unfounded remarks about alleged confusions in the English unit system. But there is no confusion. Practically everyone carries at all times two reasonably accurate standard feet, and miles are what it takes a thousand paces to cover. Arguments that the English system is "unscientific" collapse when it is realized that much of that system is based on binary arithmetic (64 pints per bushel, 1/32 in., etc.) or the duodecimal system, both of which possess distinct mathematical advantages. It is disheartening to see metrification pleas emanating from the same nation that gave us Lord Kelvin's absolute foot-grain-second (fgs) electromagnetic units, a system I find quite handy.

Spurious appeals to the French Revolution will not do. Their ten-day week and similar inanities never caught on. The

metric measurement was at first voluntary in France since it was assumed that "logic" would prevail. In fact, logic did prevail — people simply ignored the fool units until the powers-that-be made them compulsory in 1840. Things have not changed. Only where the crushing weights of state power bears down on a helpless citizenry does the metric system prevail. Perhaps it is time for a counter-revolution.

NERC and unions

SIR—Your report of Professor E.R. Oxburgh's Royal Society paper, on UK geophysics (*Nature* 27 June, p. 709) may have given readers a false impression of trade union attitudes within the Natural Environment Research Council (NERC).

Oxburgh's fears that NERC's commercial competitiveness is constrained by "labour legislation and trade union agreements" are unfounded. All employers are, or course, bound by legislation and the parlous state of NERC's finances can hardly be sought in this direction. The NERC trade unions may be forgiven for feeling slightly flattered that Professor Oxburgh thinks us able to compel our management on the topic of short-term contracts of employment. The truth is, however, that present agreements on so-called "period appointments" were reached after much disquiet had been expressed both by staff and management.

Management was concerned that people working on short-term projects spent one year reading around the topic, one year working upon it and their final year looking for another post. The NERC trade unions agreed that this was an inefficient way of deploying our resources and were naturally concerned at the lack of job security and pension rights. It was against this background that a code of practice was agreed.

Whilst chairman, Sir Hermann Bondi consistently defended present practices. Far from compelling the British Geological Survey to take short-term staff onto the permanent complement, trade unions have often protested to management when such action has been taken summarily and without following due procedures allowing for full competition for filling vacant posts.

Trade unionists within NERC are fully committed to working for an efficient and vital organization. It is a discredit to the scientists and support staff who make up those unions to cast them as obstacles to the realization of NERC's potential.

Ferroelasticity comes of age

Crystals that can be made to twin under the influence of mechanical stress have been known for some time; neodymium pentaphosphate may become the basis of novel optical and acoustic devices.

WHAT is the object shown in the accompanying photograph? An optical grating perhaps? Then something has gone wrong with the ruling engine, for the rulings are not uniform in width but wedge-like, making a zig-zag pattern across each strip of the object. Yet potentially, the first guess is correct.

What the photograph shows is the pattern of transmission of polarized light through a single crystal of neodymium pentaphosphate (NPP) prepared by a technique described by Stephen Meeks and B.A. Auld in the 15 July issue of *Applied Physics Letters* (47, 102; 1985). The width of the periodic bands ranges from roughly $18\text{ }\mu\text{m}$ to $6\text{ }\mu\text{m}$ (on the right).

What excites Meeks and Auld is that they have a technique by which the spacing of the grating elements can be systematically changed, or tuned, at least for spacings greater than $0.5\text{ }\mu\text{m}$. Since NPP is also a laser material, and one with an exceptionally low threshold because of the exceptional fluorescence of the material, they hope to be able to have a laser with a built-in optical grating which can, moreover, be instantaneously tuned. But the material has other obvious applications in, for example, the construction of acoustic gratings and filters.

This curious development has been on the cards for the best part of a decade, since the recognition that the pentaphosphates of the rare earth elements (but also those of lead and bismuth) are capable of forming crystals that are ferroelastic, which is merely a way of saying that they may be induced to change their microscopic state by means of macroscopic elastic stress. Indeed, NPP crystals, which tend to be produced as thin plates that may be up to a centimetre long, can be flipped from one stable state to another by forces that seem quite trivial; stroking the surface of a crystal with a toothpick seems to suffice.

The explanation of this peculiar behaviour of NPP, and of materials like it, seems first to have been given by H.P. Weber, working at Bell Laboratories in the 1970s (see, for example, Weber, H.P., Tofield, B.C. & Liao, P.F. *Phys. Rev. B*11, 1152; 1975). The essence of the explanation is that NPP may crystallize in the form of monoclinic crystals which differ hardly at all from the higher orthorhombic symmetry. Indeed, X-ray diffraction shows NPP to have pseudo-orthorhombic symmetry; numerically, the

monoclinic angle differs from 90° by roughly $\frac{1}{2}^\circ$ only.

The result is that parts of a crystal may be pushed, literally or mechanically, from one monoclinic form into the other lying the other side of the orthorhombic ideal. The result is a twinned crystal. The patterns that Meeks and Auld have produced at the Applied Physics Department at Stanford University are nothing but those

of crystals in which twinned structures alternate with each other across the width of the whole specimen.

All this is accounted for by the atomic structure of the crystals. NPP is $\text{NdP}_5\text{O}_{14}$, and the monoclinic forms of the material are built, on an atomic scale, from tetrahedra of PO_4 ions linked together by the commonality of oxygen atoms.

The basic building-block of the crystal structure is a more or less flat ring of eight tetrahedra; these units are linked to other identical rings by means of pairs of phosphate tetrahedra. The result is a ribbon of linked phosphate tetrahedra some $13\text{ }\text{\AA}$ across and arbitrarily long. In the bulk crystals, which are cemented together by the appropriate disposition of Nd ions, the ribbons are laid down parallel to each other to form sheets, and then these sheets are piled on top of one another.

The origin of the ferroelasticity of NPP lies in the asymmetry of the eight-membered phosphate rings, which are so constructed as to bring one pair of oxygen atoms (on opposing tetrahedra) too close together for comfort. The result is a distortion of the ring from the most symmetrical arrangement that might be attained. The distortion is only small and, as might be expected, it disappears as the temperature is increased, which is why monoclinic NPP is transformed into rhombic NPP at a little above 140°C .

The formation of twins in such a crystal is then easily accounted for. The distortion of the basic phosphate ring in the crystal structure can be accomplished either by moving the tip of one of a pair of opposing tetrahedra to the right and the

other to the left, or vice versa. So one part of a monoclinic crystal may consist of rings distorted in one sense and the remaining rings distorted in the other. The horizontal stripes in the figure are such twins.

Because of the layered structure of NPP, however, it is clear that another form of twinning is possible, essentially because the registration of successive planes of phosphate ribbons can be changed relative to each other. Twinning of this kind, which is not in practice as easily accomplished, accounts for the vertical boundaries in the illustration.

The trick that Meeks and Auld now boast of is that for tuning the periodicity of the wedge-shaped alternating domains of crystal structure in twinned relationship to each other. Generating a pattern (such as that in the illustration) is largely a matter of supporting a plate-like crystal at two points and pressing between the supports.

The use of the word domain is deliberate; Meeks and Auld point out that the effects of a first application of stress are to cause the formation of a number of flat lens-shaped bubbles of different twinned crystal structure which, like ferromagnetic domains, appear to repel each other, so that their spacing is reasonably regular. The greater the shear stress on the crystal, the smaller the spacing. When the bubbles fill the space between the pressure points, they coalesce into a zig-zag pattern as in the figure, and when the stresses are removed, that part of the pattern outside the pre-existing stress pattern will be found to be permanently preserved between two immobile vertical twinning walls.

Tuning seems to be similarly straightforward. To increase the spatial frequency of a pattern of stripes, it is merely necessary to regenerate the original stress pattern and to move whichever stress point lies near the vertical boundary so as to compress the area occupied by the zig-zag pattern.

As things stand, NPP crystals are plainly a long way from being practical devices with any kind of function. The regularity of the spacing of alternating wedges of twinned crystal has, however, been confirmed by the demonstration that they are capable of yielding sharp Bragg diffraction spots (with optical light, not X-rays). The interest of a laser which is also a tunable optical grating will require time to be fully appreciated. Intrinsic unprecedented collimation is presumably only one of the potential benefits. **John Maddox**

Ecology

Water temperature and fleas correlated in Lake Windermere

from John H. Steele

WE ARE becoming much more conscious of, and interested in, changes in climate — both the long-term trends and the shorter fluctuations. Although the most direct evidence derives from records of temperature, wind or rainfall, it is often necessary to use biological indicators, such as tree rings or changes in composition of aquatic communities. But that raises questions of the relation between physical and biological variability, witness the arguments about whether 'punctuated equilibrium' is internally driven by ecological or evolutionary processes or is caused by external or even extraterrestrial physical events. Thus direct evidence of relations between climate change and biological patterns, such as the correlation reported on page 536 of this issue between the water temperature in June of Lake Windermere, in northern England, and the abundance of the dominant zooplankton, *Daphnia hyalina*, is always welcome.

Both the temperature and plankton data presented by D.P. George and G.R. Harris show a ten-year cycle over the period 1940–80. There are two other interesting factors noted in the paper. First, the population of the dominant fish, the perch, does not have a similar pattern, indicating to the authors that the fish neither influence nor are influenced by plankton density, at least on these time scales. Second, the ten-year cycle is similar to that observed in the northeast Atlantic, implying a large-scale relevance to the lake's physical and biological data.

Variability in biological data can be related to internal features of the ecological system as well as to external forcing. There has been a longstanding interest in using simple ecological models to investigate cyclical behaviour in populations but there is little acceptable evidence of how this actually happens without changes in the populations' environment. There are still arguments about the explanation of the lynx-hare cycles in the Arctic and the fairly regular outbursts of the spruce budworm. Cyclical behaviour in a particular time series of data may also disappear or be less obvious when more data become available. Thus an ecological system may appear to 'resonate' with its environmental forcing before lapsing back into irregular variations. A ten-year cycle in a forty-year data set raises questions that may be answered only by more observations or by specific causal explanation.

Equally intriguing is the authors' comparison of the temperature cycle in Windermere with that in the eastern North Atlantic, so that the lake data "reflect a

much wider pattern of climatic variation" with a period of approximately ten years. Though one's first thought may be of a possible relation to sun-spot cycles, air temperature records for central England over the past 300 years do not show this periodicity (Shapiro, R. *Q. J. R. met. Soc.* **101**, 697; 1975). Furthermore, a record of sea temperatures off Plymouth over ninety years shows quasi-cyclical changes that go in and out of phase with the sun-spot cycle (Southward, A.J. *Nature* **285**, 361; 1980).

If the correspondence in lake and sea temperatures is not mediated directly by air temperature, what other factors might be involved? In an analysis of the changes between 1873 and 1972 of the intensity of westerly winds over the North Atlantic, T.J. Makrogiannis *et al.* (*J. Clim.* **2**, 159; 1982) found, although they could not

easily explain, a ten-year periodicity. As George and Harris suggest, the link between temperatures in Windermere and the open ocean may arise indirectly through comparable variations in wind-induced mixing in the two very different aquatic systems. Again, there are questions about which processes in the ocean and atmosphere could generate such long-period cycles. Is there a northern oscillation like the southern oscillation associated with El Niño? It must be noted that all the longer-term data sets have several spectral peaks at frequencies from months to a few decades. Thus the interactions between oceans, atmosphere and lakes occur over a wide temporal range and will affect the biology in different ways.

These correlations between physical and biological events and between the open ocean and a mountain lake are tantalizing. Raising more questions than they answer, they demonstrate the need not only for longer data sets in aquatic environments but especially for studies of the causal interactions between land, ocean and atmosphere. □

John H. Steele is Director of the Woods Hole Oceanographic Institution, Woods Hole, Massachusetts 02543, USA.

Cosmology

How did the Universe begin?

from I.G. Moss

BY AND large, cosmologists have become accustomed to the idea that the Universe began with an initial singularity of infinite density and infinitesimally small volume. This idea is strongly supported by the singularity theorems which Penrose and Hawking produced in the 1960s. But now, in an about-face that has come from a consideration of quantum mechanical effects on the origin of the Universe, Hawking and colleagues suggest that the Universe had a non-singular beginning followed by a period of very rapid expansion (which goes under the name of inflation) and then a transition to the conventional development described by the hot big-bang model. A longstanding problem of cosmology, to explain the origin of the density fluctuations that are needed to account for galaxies, is solved along the way by quantum fluctuations².

The problems of combining quantum mechanics with Einstein's theory of gravity still remain to be solved, but there does exist a coordinate-independent formalism of quantum mechanics (that is, one consistent with general covariance) invented by John Wheeler³ and Bryce DeWitt⁴. This very beautiful theory deserves to be better known. The wave function is a function of the geometry of space and of the matter fields. As a consequence of general covariance, the wave function satisfies a wave equation, known as the Wheeler–DeWitt

equation, which turns out to be the gravitational analogue of Schrödinger's equation. Thus, choosing the boundary conditions for this differential equation is analogous to choosing the initial conditions in a classical treatment of cosmology.

It was hoped that there would be only one solution of the Wheeler–DeWitt equation consistent with reasonable regularity conditions on the wave function but, as yet, there is no evidence that this is the case. Instead, Stephen Hawking has formulated a principal of quantum cosmology which produces one solution with particularly nice properties⁵. This wave function is constructed from the sum of many amplitudes for space-times with finite volume but no boundary. Hawking describes this by the cryptic statement⁶: "The boundary condition of the universe is that it has no boundary". His wave function is non-singular at space-time singularities and also has the property that it puts the matter fields into their ground state initially.

The first calculations of the wave function for the inflationary universe using Hawking's principle^{7,8} were performed on a model of the universe in which only a very small number of degrees of freedom are included (mini-superspace). These wave functions show recognizable features that correspond to the inflationary era and the matter-dominated era of

the universe. According to semi-classical approximations, they seem to correspond to classical universes that start out from a fixed size, at first expand exponentially but thereafter expand in the cycloidal form of matter-dominated universes, as shown in the figure. The wave function can therefore be interpreted in terms of universes which nucleate from nothing and eventually return to nothing.

An interesting problem of the origin of the Universe concerns the nature of time. Because the Wheeler-DeWitt formalism is coordinate free, time can only enter implicitly by the identification of some degrees of freedom as a kind of clock. If the volume of the universe is used as a clock, then it can be shown by a suitable approximation that the Wheeler-DeWitt equation reduces to the familiar Schrödinger equation for the matter degrees of freedom. In this case, we recover the standard physical models. However, the approximation breaks down when the universe is very small and it seems that the concept of time as we know it also breaks down.

A remarkable property of the Hawking wave function is that it is time-symmetric in the sense that probabilities for matter-field configurations are independent of whether the universe is expanding or contracting. According to Hawking⁶ this implies that the arrow of time defined by entropy increase would be reversed during contraction, which is reminiscent of the ideas of Gold and others in the 1960s.

For a classical universe it can be shown that this implies a boundary condition at the moment of maximum expansion¹⁰, which is unusual because it lies in our future. This interpretation is not forced upon us if the contracting phase collapses to a point: the wave function may then still be time-symmetric because it includes contributions from many classical universes. Half of these are completely time-reversed, but seem normal to time-reversed observers living inside them.

There still remain problems with quantum gravity. Fortunately, since these come from the interactions between gravitons, a treatment of the graviton degrees of freedom in a linearized approximation is possible. This calculation has been performed by Hawking⁷ among others. The result is that the amplitudes of these wave-like degrees of freedom have a gaussian probability distribution. The variance of this distribution corresponds to a scale-free spectrum of density fluctuations, which is quite acceptable for an explanation of the large-scale structure of the

universe, including galaxies.

On length scales larger than 100 Mpc, these inhomogeneities are still small at the present epoch. Therefore Hawking's principle of quantum cosmology, taken together with inflation, implies that the Universe is homogenous when averaged over large length scales.

Another difficulty is the interpretation of the wave function of the whole Universe, which may be expected to include observers of the Universe such as ourselves. If this is so, it leads to a 'many-worlds' interpretation of quantum mechanics. Furthermore, it turns out that the Hawking wave function is a superposition of quantum states that are peaked around different classical solutions of the form shown in the figure. Our view of the Universe is therefore as much a consequence of the complicated interaction between ourselves and the rest of the Universe as it

is a consequence of the state of the whole Universe. When calculating the spectrum of density perturbations, for example, there is a possibility that fluctuations between different classical universes may affect the result. □

Proto-oncogenes

Clues to the puzzle of purpose

from J. Michael Bishop

THE oncogenes of retroviruses arose by transduction of normal cellular genes that are in consequence known as proto-oncogenes. What are the physiological functions of proto-oncogenes, why have they been conserved across phylogenetic time, and why do their viral offspring wreak such havoc? The most conspicuous property of viral oncogenes is their ability to impose mitosis on cells that might otherwise be at rest. It seemed reasonable then to suppose that proto-oncogenes would also encode mitotic signals. But a story now emerging suggests that this is not the case for *c-src*, the first proto-oncogene to be discovered. Two papers in this issue provide the latest chapters^{1,2}.

Cotton and Brugge began the tale by showing that pp60^{c-src} (the protein-tyrosine kinase encoded by *c-src*) is particularly abundant in brain, retina and spinal ganglia — tissues not renowned for their mitotic activity³. Sorge *et al.* followed with the demonstration that differentiated and mitotically silent neurones are responsible for the abundance of pp60^{c-src} in the retina⁴. Whatever the function of *c-src* may be, it is apparently required in cells that are no longer dividing. Brugge and her colleagues have now extended this conclusion to include both neurones and astrocytes cultivated from the central nervous system of rats and, in the process, have added new complexity to the plot¹.

The pp60^{c-src} protein isolated from neurones displays two distinctive properties: a presently mysterious structural modification in its amino-terminal domain⁵; and substantially greater specific enzymatic activity than in other tissues¹. Changes of this sort are familiar to mavens of *src*. Phosphorylations of tyrosine in

the amino-terminal domains of pp60^{c-src} and pp60^{v-src} (the product of the viral oncogenes, *v-src*) seem to increase the kinase activity of the proteins^{6,7}; the kinase activity of pp60^{c-src} is enhanced by binding to the middle T antigen of polyoma virus^{8,9}, perhaps by an influence on post-translational modification⁹; and the basal enzymatic activity of pp60^{c-src} is reputed to be well below that of its viral cognate¹⁰. If there is a unifying theme here at all, it seems to be that post-translational modifications brook large in regulating the physiological activities of *c-src* and *v-src*. But simple changes in activity may not be the whole story, since *c-src* alone is unable to transform cells to neoplastic growth, no matter how robust its expression^{11,13}. The mutations that distinguish *v-src* from *c-src*¹⁴ apparently endow the viral gene with the ability to transform cells and cause tumours¹², and this could well be due to novel substrate specificities conferred on pp60^{v-src}.

Brugge and her colleagues believe (but cannot yet prove) that the structural modification of pp60^{c-src} they have discovered in neurones is responsible for its increased specific activity, though the modification is not phosphorylation of any sort. Their findings further dramatize the contrast between *c-src* and *v-src* by demonstrating again that perhaps no extreme of protein phosphorylation by pp60^{c-src} can elicit cellular proliferation; and they reveal a duality of control over *c-src*, since there is abundant expression of the gene in both neurones and astrocytes, but post-translational modification and augmented kinase activity of the gene product only in neurones. These subtleties exemplify the sorts of fine-tuning that operate to govern

the performance of cells.

Is *c-src* master or servant? Does it command any of the events essential for the differentiation of neuronal cells, or does it merely help to sustain the routine metabolism of the cells once they have reached a preordained point in development? Alemà *et al.* have addressed this issue tangentially by deploying *v-src* in PC12 rat pheochromocytoma cells, which assume at least some properties of sympathetic neurones when exposed to nerve growth factor². It is already known that *v-src* can meddle with differentiation in a variety of developmental lineages, either blocking or reversing differentiation¹⁵. Alemà *et al.* now complete the cycle (to use a metaphor that will reverberate fully only for cognoscenti of American baseball) with their discovery that expression of *v-src* in PC12 cells, on the contrary, induces differentiation without assistance from nerve growth factor. The phenotypes elicited by *v-src* and nerve growth factor appear quite similar, within the confines of a rather limited survey of markers. One point of interest that apparently has yet to be examined is whether the effects of *v-src* on PC12 cells are reversible. Does *v-src* drive the cells beyond a point of no return in the schedule for development, or are the pleiotropic (and potentially reversible) effects of phosphorylation by pp60^{src} directly responsible for the phenotypic changes that connote differentiation? The question could presumably be answered by the use of conditional mutants of *v-src*, much as Alemà *et al.* have used such mutants to prove that *v-src* is responsible for differentiation in the first place.

The potential parallels between the findings with PC12 cells and the expres-

sion of *c-src* in neurones are obvious. The modified form of pp60^{src} found in neurones could be a functional analogue of pp60^{src}, the effect of *v-src* on PC12 cells a facsimile of the role played by *c-src* in normal differentiation. There is an important caveat, however, that Alemà and his colleagues acknowledge but perhaps dismiss too lightly. The products of *c-src* and *v-src* are not physiological equivalents. The actions of *v-src* on cells are those of a mutant gene, demonstrably anomalous and thus ill-suited to exemplify the functions of *c-src*. We need the sorts of clues provided by the work reported here. But more decisive means will be required to solve the puzzle of purpose that has been posed since the moment *c-src* first came into view. □

Tropical diseases

Progress on *Theileria* vaccine

from Peter C. Doherty and Ruth Nussenzweig

EAST COAST FEVER (ECF), caused by the blood-borne protozoan parasite *Theileria parva*, kills approximately 500,000 cattle each year in Eastern and Central Africa. The task of finding a solution to this problem by contemporary scientific methods has been given to the International Laboratory for Research on Animal Diseases (ILRAD), which started in Nairobi 10 years ago and currently employs about 40 scientists working in collaboration with other groups involved in research and field-control measures throughout the ECF-endemic area of Africa, and with scientists in Europe and the United States.

The approach to solving ECF is determined by the biology of *T. parva*. The parasite is transmitted by the three-host tick *Rhipicephalus appendiculatus*, which feeds on infected cattle and ingests erythrocytes containing piroplasms. Buf-

falo, which are much less susceptible to the disease than are cattle, act as a wild-life reservoir. The parasite undergoes various developmental stages in the tick, culminating in the development of sporozoites in the salivary gland. The sporozoites infect other cattle through tick bites and rapidly invade lymphocytes, which replicate in concert with parasite schizonts and essentially become leukaemic cells. Enormous numbers of these lymphoblasts are formed, followed by massive lympholysis, extreme debility and, in most cases, death of the host animal 2–4 weeks after infection. It is not known whether T and B cells are targets for transformation *in vivo*, but all transformed cells differentiate to express T-cell surface markers, including thymus-leukaemia-like antigens. Tumorigenicity is a function of the continued presence of the parasite, because treatment of cloned cells *in vitro*

with cytochalasin B or theileriocidal drugs results in loss of transformed phenotype in the progeny cells that no longer contain schizonts.

The first obvious place to interrupt the parasite cycle immunologically is to prime cattle to reject the tick, but this approach has had only limited success. Recent efforts have been made to immunize cattle against the sporozoites. Mapping the schizont with a battery of monoclonal antibodies indicates that there are at least four different strains of *T. parva*, but monoclonal antibodies against the sporozoites do not distinguish between the strains^{1,2}. Furthermore, these antibodies, and sera from immune cattle³, will neutralize sporozoite infectivity *in vitro*. Such neutralization also seems to occur *in vivo* in cattle with high titres of anti-sporozoite antibody, although more satisfactory experiments to address this point are in progress. The target for the relevant antibody is evidently a molecule of relative molecular mass 68,000 which seems to be expressed both internally and on the surface of the sporozoite. Ultrastructural analysis has shown that the parasite surface antigen transfers to the plasma membrane of the host cell as the sporozoite invades, and remains on the surface of the lymphocyte for some time. Biotechnology techniques will allow large amounts of the sporozoite molecule to be produced for further analysis and possible vaccine production; both complementary DNAs and genomic libraries have been prepared and experiments are in progress to identify the relevant genes.

The obvious problem for the development of a sporozoite vaccine is to induce a level of immunity such that insufficient sporozoites escape neutralization and so establish a lethal infection. Cattle can, however, control infections induced experimentally by small numbers of autologous schizont-infected cells⁴. The alternative is to concentrate on eliminating the schizont-transformed lymphocyte. The infected cells can be killed by *Theileria*-specific, major histocompatibility complex (MHC) restricted, cytotoxic T lymphocytes (CTL)^{5,6}. Such effectors are readily generated *in vivo*, although there are problems in maintaining CTL specificity following restimulation of primed lymphocytes *in vitro*. Part of the difficulty for ILRAD is that it must develop the basic reagents and techniques for prosecuting bovine cellular immunology. In this context, ILRAD hopes for some technology transfer from Africa to the developed countries.

As with many murine CTL systems, there has been no success in developing monoclonal antibodies that detect *Theileria* parasite antigens on the surface of transformed cells. Identification of the relevant gene product may only be achieved by the application of molecular biology, as was also the case for some murine systems^{7,8}.

A genomic library has been constructed from piroplasm-infected red blood cells in a λ -phage expression system and is being probed with monoclonal antibodies directed at schizont antigens. If the system is similar to that of influenza virus⁹, the CTL may be specific for changes induced by a parasite molecule that is readily detected within the cell by antibody binding but is not easily demonstrated on the outside of the plasma membrane.

Assessment of the relevance of any schizont gene product for T-cell recognition required the solution of several technical problems. The first is the supply of readily available CTL clones for assessing antigenicity. The techniques for establishing concanavalin A-stimulated and alloreactive T-cell clones from cattle have now been established at ILRAD, so this is unlikely to prove a long-term difficulty. The second is the need for class I MHC-compatible bovine cells that can be transfected with parasite genes and then tested with such CTL clones. An alternative may be to exploit the vaccinia virus gene transfer system which has worked well with, for instance, human hepatitis¹⁰. Virus vector technology may ultimately provide the solution to the delivery of both sporozoite and schizont genes to exposed cattle.

Genetic engineering approaches to developing both sporozoite and schizont-specific vaccines offer the possibility of a long-term solution which could take 5–10 years to perfect. A more immediate control measure is already available; that is, to infect cattle with sporozoites and treat them concurrently with long-acting oxytetracycline, providing a solid immunity (at least to homologous strains). The availability of schizont-specific monoclonal antibodies for analysing cross-protection patterns and for typing strains endemic to a particular area, together with the development of better drugs for treating the early stages of ECF, make this a feasible protocol.

There are good reasons for using the

infection-treatment method only as an interim procedure. One is that the sporozoites for infection can only be supplied as an homogenate of tick salivary glands. There is also currently no satisfactory way of titrating *in vitro* for vaccine standardization, although there are possibilities of using anti-sporozoite monoclonal antibodies or a lymphocyte binding assay. Another difficulty is that delivery of such a vaccine in many field situations is both cumbersome and demanding. Even so, the procedure could be economically feasible as there would be less need for costly dipping to control ticks. Unfortunately early indications are that a reduction in dipping of ECF-immune cattle leads to the emergence of other tick-borne diseases. Two such diseases, babesiosis and anaplasmosis, are the subjects of investigation in other laboratories but the third, heartwater (caused by the rickettsia *Cowdria ruminantium*), is at present little studied.

Has the experiment of ILRAD been a success? It has made initial progress in the

analysis of ECF and is now a focus for research training and contemporary biotechnology transfer in Africa. It is also nurturing the emergence of well-trained African researchers, and giving a number of young scientists from the developed countries the opportunity of first-hand experience in working with disease problems of this nature. The answer, then, must be yes. □

Archaeology

Early man as complex hunter

from Clive Gamble

PREHISTORIC archaeology is beginning to show that human societies dependent on foraging and hunting existed at different levels of organizational complexity. This conclusion is far removed from the generally accepted notion that all hunting and gathering societies were the same and did not change until the appearance of agriculture.

Although research into the origins of hominids and human culture has captured most attention, equally important, but less publicized, advances have been made in studying the archaeology associated with *Homo sapiens sapiens*. For most parts of the world this covers a period starting at least 40,000 years ago, except in North America, where R.D. Guthrie¹ argues that the earliest colonization occurred about 12,000–14,000 years ago.

The comparative study of hunter-gatherers on a world scale began over 20 years ago with the symposium *Man the Hunter*². Many of the concepts emerging since then have formed the basis for research that has dramatically changed archaeological practice and analysis. These include ethnoarchaeological studies of modern foraging groups, performed most productively in Alaska, the Kalahari and many parts of Australia. R. Lee (in ref. 2) used a world sample to examine the importance of particular subsistence activities — hunting, fishing and plant foraging. This work was the starting point for many studies of primary adaptive behaviour related to resource management and procurement. Such behaviour is now commonly discussed in terms of a

world model of hunters and gatherers, where variation in food-searching behaviour is related to survival strategies to cope with the differential distribution of energy and usable food resources in global environments. In archaeological terms, these highly differentiated strategies left behind distinctive signatures, as measured by the density and distribution of flint artifacts within regional territories, evidence that groups used the tactics of mobility, group size and composition and inter-group alliances as buffers to enable them to survive in the Pleistocene.

At this symposium, M. Sahlins (in ref. 2) characterized hunters and gatherers as the 'original affluent society', based on the short working week of some of the Kalahari and Arnhem Land societies. Affluence has also been recognized as a feature of coastal groups in north-west North America. Here, bulk storage of salmon apparently provided a subsistence base for the elaboration of material culture, a high degree of sedentary behaviour and the degree of social ranking (including slaves) in these societies. Such societies' lifestyles have frequently been regarded as exceptional in comparison with the nomadic style of other contemporary foraging groups.

Such societies have been re-examined recently³ in terms of the emergence of cultural complexity in the New and Old Worlds. Cultural complexity is measured through population density; widespread exchange systems using raw materials as well as items as diverse as pottery vessels, ear-spools and alligator teeth; evidence

Electron micrograph of a bovine lymphocyte invaded by several sporozoites of *Theileria*, $\times 10,000$ (courtesy of ILRAD).

for permanent and larger settlements; the appearance of artistic codes used to transfer information; and harvesting mechanisms such as eel traps, which require inter-group organization to use efficiently the high-energy, small-package food supplies in the low trophic levels. Some of the clearest measures of complexity come from the analysis of cemeteries like that at Oleneostrovski mogilnik in northern Russia, where the differential distribution of grave goods and the spatial location of individuals indicate hereditary social positions among this group of Holocene boreal forest foragers⁴.

These findings confirm L. Binford's⁵ earlier characterization of the stone tool industries of the European upper Palaeolithic as reflecting a relatively complex social geography compared with earlier traditions. M. Conkey argues that it is no longer possible to characterize societies of the Upper Palaeolithic or Mesolithic periods by a single social type (in ref. 3). Instead, there existed a mosaic of social structures bound together on a large spatial scale by ramifying networks of alliances. Consequently, complexity has to be measured at both a regional and continental scale. As B. Bender (in ref. 3) points out, the characteristic complexity in these worlds of hunters and gatherers was for shifting emphasis within a regional landscape, as power structures emerged at a local level for relatively short periods of time. These must be compared with the world that hunters and gatherers are found in today and in the historic and later prehistoric pasts. Here, any transformation to complexity has occurred within the arena of a much more complex social geography, including state organizations of immense elaboration and complexity⁶.

Recent work has thus swept away lingering notions that complexity and intensification in social and economic behaviour arrived with the introduction of agriculture. The archaeological definition of agriculture is now unclear, as prehistoric hunting and gathering societies expanded to fill the ethnographic spectrum that has previously been accorded to their more 'sophisticated' successors.

The investigation of the causes for the emergence of cultural complexity is still beginning. One fruitful line of enquiry, proposed by G. Johnson⁷, is that of scalar

stress, which arises as groups settle down and form larger integrated units. This results in information-processing problems when more than six such units have to be integrated. One solution is the inauguration of hierarchies, as they are more efficient at processing information and hence solve some of the problems associated with sedentism.

D. Brown and J. Price conclude³ that what emerges from these discussions of cultural complexity will define the archaeological units of analysis on which the locus of explanation will eventually settle. There are two such units: the first emphasizes the social aggregate and is investigated at the macrosystemic level, which can be done by investigating sites in regions and interpreting them as group residues; the second is the social 'molecule', where selection occurs at the level of the individual and family and minimizes group stress in the short term. This microsystemic approach still awaits the development of archaeological methodology to realize its full potential. The combination of both scales may elucidate changes occurring in the varied timescales of the archaeological record.

When viewing complex societies from

the perspective of the hunter-gatherer, agricultural communities appear to be the failures, rather than the successes, of prehistory in that they had to invent or adopt agriculture, because their systems were breaking down both at the group and individual scale. Out of such stress came the complexity that is now recognized in the archaeological record. The challenge is to understand precisely how present-day models have previously prevented us from appreciating the diversity of the prehistoric world of the hunter and gatherer by obscuring the questions at the very heart of archaeological inquiry — why does change occur and why does variation in human societies exist? □

Drilling technology

Well-loggers and scientists

from Roger N. Anderson

DRILLING for oil is fundamentally different from drilling for scientific purposes. Although an understanding of the geology penetrated by the drill bit is a requirement for the discovery of new oil and gas reserves, the economics of drilling have caused the oil industry to develop an extremely sophisticated remote method for determining the physical and chemical states of rock after they have drilled through it as fast and as deep as they can. It is simply too expensive to cut core samples during the drilling of an oil well. This process eliminates the traditional primary product required by geologists for scientific investigation — the core — and substitutes the 'log'. A recent symposium* examined the differences that are inherent in logging for purely scientific as opposed to commercial objectives.

The technologically advanced well-logging service is possibly the single most important operation in the oil industry, as well as being the most profitable. The devices monitor electrical, sonic and nuclear measurements made up and down an oil well from the surface, producing a log of the geology without the need for samples. These logs detect lithology, formation strike and dip, porosity, fractures and, most importantly, the chemical composition of the fluid filling the pore spaces of

the rock — that is, they can show whether oil and gas are present.

In contrast, drilling deep into the Earth for scientific purposes has historically depended on core for the determination of these geological characteristics. Without the pressure of time, or the requirement of great depth, scientists can slowly cut their core as the well progresses. Most scientific drilling has been the result of the Deep Sea Drilling Project, where holes are relatively shallow even though they are beneath great depths of water. Now that several countries are involved in deep continental scientific drilling, the high costs of coring are causing the scientific community to devote more attention to how logs can be used to supplement and support coring for the determination of the geology of the deep crust. Interestingly, logs measure parameters at different scales than do cores and the two fit together to increase greatly the amount of data returned per foot of well drilled.

Often, an oil company's 'noise' is a scientist's 'signal'. Take the most sophisticated of well logs developed to date — nuclear bombardment of the rock. New techniques presented at the symposium by Gordon Pirie, Mike Herron and Charles Flaus (Schlumberger) showed that true neutron activation analysis of the elemental chemistry of the rock can now be accomplished with a logging tool. At

Feast among the Kwakiutl Indians of the north-west coast of North America. A feature of the feast was the destruction of goods, which led to gain in status and prestige (courtesy of the Smithsonian Institution).

*'New Techniques in Scientific Well Logging', Lamont-Doherty Geological Observatory, New York, 15-16 May 1985.

Example of the new types of scientific log being developed. The nuclear and sonic logs for the depth interval 13,800–14,150 ft (below sea level) are shown for Deep Sea Drilling Project hole 556, which cuts through 37-Myr-old oceanic basaltic crust on the western flank of the mid-Atlantic ridge. The column on the left shows the degree of hydrous alteration of the basalt (strictly a measure of the chemically bound water in the rock). This is derived from determinations of the radiation arising from bombardment of the rock walls with gamma rays and neutrons from sources put down the hole. The other three columns show, from left to right, the centre frequency (in kHz), energy (in dB) and energy attenuation (in nepers per foot [1 neper = 0.8 dB]) of the refracted P (compressional) and S (shear) wave signal from a 10 kHz broadband source. The solid and broken lines are the P- and S-wave logs respectively. On the right, the lithological section from the core rock. BB, basalt breccia; PB, pillow basalt; MB, massive basalt; GB, gabbroic basalt; G, gabbro; black, serpentinite. Two serpentinite dykes show up clearly from their high alteration content and increased attenuation. The combined use of nuclear and sonic logs enables the chemical and rheological properties of the rocks to be determined without taking a core.

present, 11 elements can be 'counted' with a scintillation crystal, and this will soon increase to 30 or more with the development of cryogenic germanium counters. The oil industry, of course, concentrates on the determination of carbon and oxygen ratios in the pore fluid, whereas the geological community will use this tool for direct rock chemical measurements.

Nuclear magnetic resonance imaging similar to that being developed for medical use was described by Chuck Newman (Chevron). Here, a large magnetic field polarizes the magnetic poles within the pre-fluid and sensitive detectors measure the rate of precession of these dipoles from the oriented state back to their natural random state. This measurement is directly proportional to the permeability, or ability to flow, of the pore fluid. Scientific interest in this measurement is not in the ability of the fluid to flow into an oil well, but in the description of fluid movements within a convecting system, such as a hydrothermal circulation system within a volcano or a geothermal hot spring.

Other new logging technology involves imaging the wall of the drill hole by ultrasound. In a way that is reminiscent of the use of ultrasound to obtain non-invasive images of a fetus in the womb, ultrasonic sound is bounced off the well bore and presented as a 'television' image. Because wells are drilled with opaque mud, light cameras cannot be used. However, even if they could, they would not produce quantitative images comparable with ultrasound. Because the travel time of sound is so much slower than light, the waveform of the reflected energy can be digitized and its reflection amplitude and travel time displayed separately. Lithology, fracture locations, dip and bedding planes can be seen in the reflected image, but far

more information can be derived by the travel-time display. As Mark Zoback (Stanford University) showed, the state-of-stress within the Earth can be determined by this seemingly innocuous measurement. A display of travel time from source-firing to receipt of the reflected pulse simply gives a 360-degree picture of the size of the well bore. This caliper measurement reveals great forces pushing on the crust around the well bore from far away mid-ocean ridges, seafloor subduction zones and mantle convection. Zoback finds that borehole deformation is caused by the same forces that push and

pull the plates of the Earth's surface across each other. By sending ultrasonic sound pulses into the well, it is feasible to determine the forces which drive plate tectonics.

Seismic exploration from the surface had long been the dominant method used in the oil industry for the discovery of new subsurface accumulations of hydrocarbons. Ken Landgren and Roy Dove (Schlumberger), Joe Zemanek (Mobil) and T. K. Kan (ARCO) showed how these surface techniques can be extended into the drill hole to produce tomographic images of the geological structure surrounding the well, and to measure fundamental elastic properties of the rock such as shear-wave velocity and seismic attenuation *in situ*. Dan Moos (Lamont) and Dick Plumb (Schlumberger) demonstrated how images of the fracture distribution along the borehole can be related to sonic and seismic wave propagation along the borehole walls enabling fracture permeability of the formation to be determined.

Technology developed for a slightly different application can therefore be used in scientific exploration of the inner depths of the Earth's crust. Insight into the geology of the planet extending far from the approximately 12-inch hole cut into the rock is bound to be the result. Seldom are we presented with such an opportunity to divert already developed high technology to scientific purposes. Usually, science leads to new technology — here, technology promises to lead to new science. □

Roger N. Anderson is at the Lamont-Doherty Geological Observatory of Columbia University, New York, New York 10964, USA.

Endocrinology

Has the prolactin inhibiting peptide at last been found?

from George Fink

REPRODUCTION in mammals depends on the secretion of the gonadotropins, luteinizing hormone (LH) and follicle stimulating hormone (FSH), and of prolactin at appropriate times and in appropriate modes and amounts. The secretion of these hormones from the anterior pituitary is controlled by the central nervous system and by negative and positive feedback actions of the gonadal hormones, the oestrogens, androgens, progesterone and inhibin. The central nervous control of the gonadotropins and prolactin is effected not by a direct neural link between the brain and the anterior pituitary gland but rather by neurohormones, released in the median eminence at the base of the brain, which are conveyed to the anterior pituitary gland in the exquisite hypophyseal

portal vessels. So far, the evidence is that gonadotropin secretion is stimulated by only one neurohormone, gonadotropin releasing hormone (GnRH). The neural control of prolactin secretion is much more complex and involves both prolactin inhibiting and releasing factors¹. Peter Seeburg and his associates now show that the carboxy-terminus of human placental GnRH precursor (Fig. 1) — termed GAP for GnRH-associated peptide — inhibits prolactin and stimulates gonadotropin secretion in primary cultures of anterior pituitary cells². Seeburg *et al.* suggest that GAP may be the sought-after prolactin inhibiting factor and argue that their findings simplify our understanding of the neural control of gonadotropin and prolactin secretion. But do they?

The most important function of FSH is to stimulate the growth and maturation of ovarian follicles in the female and spermatogenesis in the male. LH causes ovulation and the formation of the corpus luteum in the female and stimulates androgen secretion by the Leydig cells in the male. The ovulatory surge of LH is massive³ and can be triggered either reflexly by copulation as in the cat, rabbit, vole and tree shrew, or spontaneously, as in man, sheep and rat, by a positive feedback cascade (Fig. 2). Prolactin is primarily concerned with the production of milk and is therefore essential in mammals for the survival of the young after birth. In some eutheria, such as the rat, prolactin also maintains the corpus luteum (hence its older name, 'luteotrophin'), and in marsupials it virtually runs the whole reproductive cycle⁴. The 'basal' secretion of the gonadotropins and prolactin is pulsatile. In the case of the gonadotropins this is thought to reflect the importance of frequency modulation of gonadal function by the brain-pituitary system, seen most convincingly in seasonal breeders⁵.

Under certain conditions there is an inverse relationship between prolactin and gonadotropin secretion. In the human female, this is most prominent during lactation ('lactational amenorrhoea'), when plasma prolactin concentrations are increased several fold by a neurohumoral reflex triggered by suckling, and in patients who have pituitary tumours that secrete large amounts of prolactin⁶. The prolactin inhibitory action of GAP, Seeburg and associates argue², could provide a simple explanation for the inverse relationship between prolactin and gonadotropin secretion. Immunohistochemical evidence suggests that GnRH and its associated peptide coexist in hypothalamic neurones⁷ and the co-release of GnRH and its associated peptide would stimulate gonadotropin and inhibit prolactin secretion. Conversely, reduced or absent GnRH and GAP release into the hypophyseal portal vessels would lead to high prolactin and low gonadotropin concentrations in plasma.

The genetic engineering used by Seeburg's group² to synthesize GAP is beautiful in design and efficiency. Their model for the action of GnRH and GAP, although it has the attraction of simplicity, does not, however, explain or take account of several important facts. First, Seeburg's group use the rat, in which a

Fig. 1 The human placental precursor for gonadotropin-releasing hormone (GnRH) showing the 56 amino acid (aa) GnRH-associated peptide (GAP) separated from GnRH by the Lys-Arg dibasic cleavage site and the Gly amide donor (from ref. 2).

Fig. 2 Schematic diagram showing the positive feedback cascade which leads to the spontaneous ovulatory surge of LH, resulting in ovulation. 17 β -Oestradiol (E₂), secreted by the ovary under the influence of basal levels of gonadotropin, triggers a surge of GnRH from the brain by an action that involves monoaminergic and opioid mechanisms. It also stimulates an increase in the responsiveness of the pituitary gonadotrophs (increased stippling) to GnRH. Pituitary responsiveness is further increased by progesterone (P). The peaks of the surge of GnRH and the increase in responsiveness coincide because of the priming effect of GnRH which thereby ensures a massive surge of LH (from ref. 3 with permission of the British Council).

massive surge of prolactin occurs concurrently with the spontaneous ovulatory surge of LH, as well with the LH surge induced by steroids in several experimental models^{8,9}. But in women there is no evidence of a significant fall in the plasma concentration of prolactin at the time of the ovulatory surge of LH. Second, it is not at all clear whether lactational amenorrhoea is produced by volleys of impulses in the afferent (neural) limb of the milk-ejection reflex generated by suckling at the nipple, by the high plasma prolactin concentrations induced by suckling, or by both. Third, elevations in plasma prolactin concentration produced by pituitary grafts under the kidney capsule significantly reduce the plasma concentration of LH and FSH, probably by reducing both GnRH release into hypophyseal portal blood and pituitary responsiveness to GnRH. For, as the authors are aware, neuropeptides such as thyrotropin-releasing factor, vasoactive intestinal peptide and the closely related intestinal peptide porcine PHI are potent prolactin-releasing factors; immunoneutralization studies^{10,11} have shown that these peptides may play an important role in the neural control of prolactin release under certain physiological conditions.

Both the prolactin-inhibitory action and the gonadotropin-releasing properties of GAP must be carefully evaluated in *in vivo* preparations under physiological conditions before firm conclusions can be drawn. In Seeburg's primary pituitary cell cultures, GAP was about 10 times less potent than GnRH in stimulating LH release. The concentration of GnRH in hypophyseal portal blood at the peak of the ovulatory surge³ is about 10⁻¹⁰ M and so if it is to play a significant role in LH release much more GAP than GnRH

would have to be released from the same neurones. Perhaps GAP is more important for releasing FSH, for which it has a similar potency to GnRH, than LH; the differential release of GnRH and GAP could then explain in part the dissociation that occurs between LH and FSH release under certain conditions.

Notwithstanding the reservations about Seeburg's oversimplified model for the relationship between LH and prolactin release, the finding that GAP may be the prolactin-inhibiting factor is important and exciting. Until now dopamine has been considered to fill that role, especially in humans where administration of dopamine receptor antagonists such as chlorpromazine and other neuroleptics, marked increases plasma prolactin concentrations, whereas dopamine agonists, such as the ergot derivative 2-bromo- α -ergocriptine (bromocriptine), significantly reduce plasma prolactin concentrations. Bromocriptine has been used as an effective treatment for amenorrhoea and infertility produced by abnormally high plasma concentrations of prolactin. It remains to be seen whether GAP, or shorter and more potent analogues of GAP, will prove to be more effective □

Labelling the axes of graphs . . .

The subject of how to express numbers on the axes of graphs — most particularly powers of ten — was the subject of letters from C. Liébecq (Nature 314, 586; 1985) and P. Luykx (Nature 315, 462; 1985). The discussion continues . . .

SIR—Liébecq and Luykx have identified a source of confusion and occasional error in the numerical tabulation of quantities. The author who wants to express concisely a quantity such as 1.5 million joules in a table has at least three choices for the column heading. They are: Energy $\times 10^{-6}$ (J); Energy (J $\times 10^6$) or Energy (MJ). In each case the numerical entry is 1.5. I suggest that the first two possibilities are correct but confusing. The third is to be preferred. A fourth possibility is to use the pure number created by dividing the quantity by its unit (Energy/MJ). Although internationally recommended, this option has been shunned by authors and editors alike.

Finally, may I express the hope that both your contributors were aware of the dual enormity of expressing "radioactivity" in "c.p.m.". Radioactivity is a phenomenon. The quantity is activity and its unit is the reciprocal second, named for this purpose the becquerel. Colloquially the unit may become transition/second, although the entity, transition (not count!), is implicit in the definition of the quantity and should not be duplicated in the unit — compare frequency in s^{-1} , no longer in cycles/second.

H. J. DUNSTER

National Radiological Protection Board,
Chilton, Didcot,
Oxfordshire OX11 0RQ, UK

SIR—In recent weeks this column has seen a complaint by Liébecq that a graph axis annotated with figures ranging from 1 to 10 and labelled "Radioactivity (c.p.m. $\times 10^3$)" is incorrectly labelled when one of the implied values is, for example, 5,000 c.p.m.; and a response by Luykx, arguing that the original labelling can be defended as long as one abandons an algebraic interpretation of the symbols. Luykx comments that "there ought to be agreement" on how to read the axis labelling.

It is clear that agreement has not yet been reached, but at least a completely rational system is available, and is particularly well described in the invaluable document *Quantities, Units and Symbols*, prepared by the Symbols Committee of the Royal Society and representing the recommendations of several international bodies concerned with the proper use of scientific notation.

The example above required the observation that if "Radioactivity = 5×10^3 c.p.m." then " $5 = \text{Radioactivity}/(\text{c.p.m.} \times 10^3)$ ". Thus, the right-hand sides of any of these last three equations are acceptable labels for an axis which includes the numerical value 5, whereas the expressions recommended by both

Liébecq and Luykx are not. Given the evident attraction of such an unambiguous system for labelling graph axes and table columns, it is indeed hard to understand why so many scientists (and all too many of the journals which publish their work) insist on using labelling systems which call for inspired guesswork on the part of the reader.

LIONEL WILSON

Department of Environmental Science,
University of Lancaster,
Lancaster LA1 4YQ, UK

SIR—Luykx concedes that Liébecq would be correct if ordinate labels were thought of as equations in the form "radioactivity = $5,000 \times \text{c.p.m.}$ ". Luykx also wishes that agreement could be reached about how such labels should be read.

On the first point, the opening, defining, sentence of the Royal Society's report *Symbols, Signs and Abbreviations recommended for British Scientific Institutions* (1969) contains the equation "physical quantity = numerical value $\times$ unit", that is, exactly in the form that Luykx considers illogical. On the second point, the Royal Society's document represents not only itself but also several leading British scientific societies including the (now) Royal Society of Chemistry and the Institute of Physics, and agrees with all of the major international bodies concerned, including IUPAC, IUPAP, ISO and CGPM. So it is clear that a considerable degree of consensus has existed for many years.

The confusion can be removed by always attaching the power to the physical quantity rather than to the unit; that is, $10^{-3} \times \text{radioactivity (c.p.m.)} = 5$ means that the radioactivity is 5,000 c.p.m. This journal (the *Australian Journal of Plant Physiology*) follows that convention as do many others. Of course, the problem can often be avoided by use of SI units and their standard prefixes.

L. W. MARTINELLI

Australian Journal of Plant Physiology,
314 Albert Street,
East Melbourne 3002, Australia

SIR—There have been two letters on the expression of large or small numbers on figure coordinates, the most recent by Luykx. He points out that there ought to be agreement on how to read them.

The *Journal of Bacteriology*, as with other American Society for Microbiology publications, follows the convention of expressing a large number such as, for example, 10^9 cells/ml, as 10 on the ordinate scale and 10^9 cells/ml or cells/ml (10^9) as the label. No " $\times$ " is used. This style is

readily understandable because it is comparable to the use of kg or mmol on a coordinate.

As to a standard, it is unfortunate that the Council of Biological Editors did not deal with this question explicitly. However, in the *CBE Style Manual* (Fifth edition, p. 79) they do set a style for units in tables, and it is this that has been adopted by the ASM for both graphs and tables.

In dealing with graphs, I suspect that the council could not agree among themselves. In the section of the manual dealing with illustrative material, 'Graphs' and 'Tables' are adjacent, and the latter includes this phrase, which in similar words can be traced back through earlier editions: "Except in rare instances, avoid numbers ($\times 10^6$), ($\times 10^{-6}$) as multiplying factors in column headings; they have caused much confusion in biological literature . . .".

DONALD P. NIERLICH

Department of Microbiology,
College of Letters and Science,
University of California,
Los Angeles,
California 90024, USA

SIR—Luykx maintains that "quantity (unit $\times$ number)" is not incorrect. His defence of this form is based on viewing the bracketed expression simply as a descriptive label which he then interprets by identifying the unit-symbol with the numerical value of the quantity.

The point at issue is, however, not correctness versus incorrectness but rather clarity versus ambiguity. I and most of my colleagues use "quantity/(number $\times$ unit)" or "quantity/(prefixed-unit)" wherein the number or prefix may be a power of 10. This accords with the Royal Society, (*Quantities, Units and Symbols*, 1971), with the policy of the Conférence Générale des Poids et Mesures, and with the International Organization for Standardization with which, in turn, almost all national standardizing bodies cooperate. I find the carefully considered conclusions of these eminent bodies less ambiguous and generally more likeable than Luykx's arbitrary preferences. I observe that some "quantities" might cause me to replace our bracketed expression by a description such as "on the Beaufort scale".

EDWIN LE FÉVRE

7 Richmond Gardens,
London NW4 4RT, UK

SIR—Liébecq and Luykx have recently suggested how to label the axes of a graph. May I suggest another method?

To continue with the example introduced by Liébecq, if one wishes to show radioactivity data in the range of 5,000 c.p.m., surely one should label the axis, "Radioactivity/ 10^3 c.p.m.", with gradua-

tions from 0 to 10. For a point lying halfway along this scale, the measured radioactivity divided by 10^3 c.p.m. gives 5, so the datum is clearly 5×10^3 c.p.m.

The approaches favoured by Liébecq and Luykx appear to have a common drawback. If on a graph or in a table one uses the heading, "velocity $\times 10^2$ (ms^{-1}), there is always the risk of some confusion. Should a reading on the graph or in the table of "48.5" be read as a velocity of $48.5 \times 10^2 \text{ ms}^{-1}$, or as $48.5 \times 10^{-2} \text{ ms}^{-1}$? Mathematical logic tells us it is the latter, but many people seem to get confused, some authors included. The use of the solidus, as exemplified above, has the advantage that the factor one needs to insert is the same factor as appears on the axis or at the head of a column, that is, "velocity/ 10^{-2} ms^{-1} ". Being completely unambiguous, this method is consequently less error-prone.

More help required on T and B cells

SIR—I read with great interest a recent letter¹ and a *News and Views* article², concerning immunological help. It was reported that a B lymphocyte can pinocytose free toxin that it binds to and present digested fragments of it on its surface. It was also reported that a helper T lymphocyte which binds to these digested fragments can help the presenting B lymphocyte to differentiate to plasma cell form in which it secretes large quantities of antibody. In the *News and Views* article several unresolved questions relating to immunological help were raised. I thought of some questions which were conspicuously absent and will here raise them and suggest hypothetical answers.

First, how is a B lymphocyte helped if it binds to a surface antigen of a pathogen? B lymphocytes might find it difficult to pinocytose a surface of any pathogen unwilling to facilitate its own destruction, and B lymphocytes are not specialized to safely phagocytose a live pathogen. Digested fragments of a pathogen presented by macrophages would not be an adequate substitute since they would not include many of the original surface antigens. Perhaps when a B lymphocyte binds to an antigen that it is unable to pinocytose, it attracts a macrophage to come and phagocytose the attached pathogen or cell, and remains with the macrophage until it places digested fragments (of the antigen and the rest of the pathogen or cell) on its surface and the B lymphocyte's surface.

Second, how is it assured that B lymphocytes will be helped if and only if they bind to nonself antigen, while still allowing pseudorandom generation of T lymphocyte antigen receptors? Perhaps hel-

per and suppressor T lymphocytes are clones of T lymphocytes which differentiated prenatally to helper or suppressor forms according to whether they did not or did bind to digested fragments of materials presented by macrophages then.

Third, how is it assured that B lymphocytes will not be helped if they bind to B or T lymphocyte antigen receptors? The diversity of helper T lymphocytes might be greatly restricted if there could be none that bound to the many different digested fragments of these receptors. Perhaps macrophages have a special ability to recognize B and T lymphocyte antigen receptors and do not present digested fragments of them; either prenatally or postnatally.

Fourth, how is it assured that B lymphocytes will not cause serious damage to self materials during an infection if they bind to an antigen common to self and pathogen? Perhaps since activated T lymphocytes would be concentrated near the pathogens, so also would their mediating chemicals, the B lymphocytes they helped, the antibodies of those B lymphocytes and the leukocytes which destroy antibody coated objects.

I wish researchers would devise experiments which clearly address the questions raised and possibly test some of the hypothetical answers suggested.

Hormone receptor-effector complex evolution

SIR—I wish to propose a theory for the evolution of receptor-effector complexes where the effector is a protein or peptide hormone. Recently, there has been much interest in the evolutionary relationship between peptide hormone effectors and their receptors. Hales proposed that peptide effectors are produced by proteolytic cleavage of membrane proteins that are evolutionarily related to receptors¹. Several recent findings concerning the peptide hormone epidermal growth factor (EGF) are consistent with this hypothesis. EGF is cleaved from a large precursor protein (prepro-EGF) that may reside in the membrane and appears to share some sequence homology with the human low-density-lipoprotein (LDL) receptor^{2,3}.

In a recent paper⁴ Baldwin noted that

Fig. 1. A single polypeptide progenitor (left) becomes a two-polypeptide complex of receptor (R) and effector (E).

there was also sequence homology between the coding region in the oncogene *c-mos* and the precursor protein for EGF. This homology did not extend into the part of the polypeptide that was cleaved into the hormone. *c-mos* is functionally related to the avian oncogene *v-erb-B* and presumably evolved from the same gene^{5,6}. In turn, *v-erb-B* has substantial homology to the EGF receptor protein⁷. This means by virtue of the relationship of *c-mos* to *v-erb-B*, the precursor protein for EGF (prepro-EGF) would have to be distantly related to its receptor as well as contain the EGF peptide.

The structure of prepro-EGF leads me to extend Hales' ideas¹ and propose a model for the evolution of receptor-effector complexes. The model is based on the fact that receptors and their effector proteins form complexes due to protein-protein interactions. When a single polypeptide chain folds, different parts of the chain interact intimately with other parts of the same chain (Fig. 1). I propose that some of the genes encoding receptor-effector complexes began as single genes that encoded single polypeptide chains that were capable of intimate folding interactions. Receptors and their effectors then evolved due to changes in the DNA that split and sometimes duplicated the progenitor gene into two genes capable of encoding two distinct polypeptides, one the receptor and one the effector, that were still capable of interacting or folding with each other. For EGF and its receptor I envision that the progenitor gene was first duplicated. The copy that became the receptor deleted the domain encoding the hormone leaving a pocket for the missing domain encoded by the duplicated gene.

However, only gene-splitting, and not gene duplication, is obligatory of the general mechanism that I have proposed. After the gene is split, differential gene expression in different cell types could then induce the synthesis of each part of the original pro-polypeptide. The interaction of the two protein parts would lead to the formation of a complex capable of performing a biological task.

The interaction of these polypeptides could effectively lead to a cell-cell or hormone-cell interaction. Regardless of whether the relationship between prepro-EGF, *v-erb-B* and a *c-mos* is real or coincidental, the simplicity of this model bears further consideration as a general mechanism for the evolution of receptor-effector complexes.

Geologists in conflict

Gordon L. Herries Davies

The Great Devonian Controversy: The Shaping of Scientific Knowledge among Gentlemanly Specialists.

By Martin J. S. Rudwick.

University of Chicago Press: 1985. Pp. 483. \$39.95. To be published in Britain in September, £36.75.

THIS is a definitive study — a work which is going to be accorded classical status. Its field, the history of the earth sciences, will never again be quite the same. So many previous historians within the earth sciences have chosen the expansive approach; they have painted in broad brush-strokes upon gigantic canvases. In 1905 Sir Archibald Geikie traced the history of geology from the speculations of Aristotle to the petrography of Henry Clifton Sorby in a mere 473 pages; in 1982 Professor Mott Greene told the story of geology from the Huttonian theory to plate tectonic theory within a volume of similar compass. Such works of sweeping purview clearly have their place, but hitherto our literature has contained few detailed micro-studies of those really crucial episodes which have punctuated the history of the earth sciences and endowed them with their present character.

Rudwick, with one major work already behind him (*The Meaning of Fossils*, first edition 1972), has sought to remedy this lacuna by focusing narrowly upon one important but now largely forgotten episode. That episode is the so-called Devonian Controversy which engaged the attention of some of the world's leading geologists during the years between 1834 and 1843. To the events of those eight years he devotes almost 500 pages and his microscopic analysis reveals exactly how there emerged the concept so familiar to us as the Devonian System. He has been able to accomplish his task because in addition to the published contemporary works germane to the controversy, there also survives an amazing wealth of manuscript material. At the outset, Rudwick reminds us of Walter Cannon's observation "that for the middle of the nineteenth century we possess the most complete documentation, for selected individuals, not only that ever has existed but that ever will exist". Certainly much that then achieved semi-permanence through committal to correspondence is today lost down the mouthpiece of Alexander Graham Bell's invention, and the kind of detailed analysis here achieved by Rudwick will for our own century probably prove quite impossible.

Recently, a number of writers — Rudwick amongst them — have emphasized that many nineteenth-century British geologists perceived their activities in terms of a military campaign designed to force nature into a revelation of the sec-

rets of her history. The analogy might be extended to Rudwick himself. He is like a military historian seeking to understand the true nature of some conflict of arms through a detailed study of platoon diaries, squadron workshop records or the signal logs of participating warships. But his object is not merely to trace the course of one particular battle; he seeks to draw lessons of significance for all those involved with conflicts in science both past and present.

Any adequate précis of so detailed and closely reasoned a work is impossible. It suffices to observe that its theme is the argument that occurred in the 1830s and 1840s over the character of the stratigraphy and structure of Devon, but, as Rudwick amply demonstrates, this was no local squabble; the debate had international ramifications extending from Russia into the New World. The protagonists were the geological giants of the day — men such as De la Beche, Lyell, Murchison and Sedgwick — and at stake were geological issues such as the truth of the doctrine of characteristic fossils, the possibility of coal-seams existing within the greywacke and the relative importance of field evidence as opposed to theory-based conclusions. At a more human level we encounter personal jealousies, priority disputes,

back-room lobbying, the suppression of one paper and the slurring of adverse field evidence in others, charges of professional incompetence and an obsessive sense of territoriality by individuals for their own field ground. In addition new light is shed upon the origin of the Silurian System and, of course, upon the birth of the Devonian System itself.

In writing the book Rudwick has enjoyed two great advantages. First, he is himself an experienced geologist sympathetic to the problems faced by those who aspire to understand rocks in the field. He knows all about rains that convert field-sheets to a pulp and about stream sections where the rocks disappear beneath the drift overburden at some vital juncture. Such a sympathy is often wanting in those who approach the history of the earth sciences via history rather than geology. Indeed, Rudwick specifically informs us that he and his wife travelled the lanes of Devon seeking "clues to nineteenth-century perceptions of its geology". Secondly, he has found that for which every author prays: an indulgent publisher. Rudwick has been allowed to present his study upon a most lavish scale. There is no hint of quibbling over wordage or penny-pinching over illustration. The introductory material occupies no less than 60 pages and the ambience of the work as a whole is reminiscent of a PhD dissertation produced by an enthusiastic student who has chosen to disregard the regulations of the Graduate Studies Committee. Sir Peter Medawar has recently declared "that nearly all books on nearly all subjects — especially the philosophical — are much too long"; whether Rudwick should have been encouraged to greater brevity can only be a matter for opinion.

Important though the book is, prospec-

Caricature of controversy — "Preconceived Opinions v/ersus Facts", De la Beche's cartoon of the scene at the Geological Society (December 1834) when his report of fossil plants in the Greywacke of Devon was criticized by Murchison and Lyell.

[De la Beche:] This, Gentlemen, is my Nose.

[His Critics:] My dear Fellow! — your account of yourself generally may be very well, but as we have classed you, *before we saw you*, among men *without noses*, you cannot possibly have a nose.

From *The Great Devonian Controversy*

tive readers may be warned that they will find much of it to be somewhat indigestible. The very scale of the feast is itself daunting as course follows course, and long sections — especially in Part 3 which analyses the forces responsible for shaping our natural knowledge — make very considerable demands upon the reader's powers of concentration. Only an insomniac is likely to select the tome as bedtime reading. Rudwick explains that he had three classes of reader in mind: sociologists and philosophers of science; historians of science; and practising geologists. The first two of these will neglect the book at their peril; Rudwick adduces from his study many lessons which have wide applications in areas of science far removed from those here discussed.

Whether he will be able to win and hold his third class of reader — the geologist — is less certain. He hopes that his book will encourage geologists to reflect upon the nature of their own research activity and he certainly invites them to contemplate some fascinating matters. Not the least of these is the question of the relationship between the human construct of a Devonian System and the actual character of events as they occurred upon the surface of the Earth hundreds of millions of years before the appearance of *Homo sapiens*. In short, in Rudwick's own words, what is the reliability of the Devonian System "as a representation of a portion of a real past history of the earth"? Few geologists will ever have been confronted by so startling and disconcerting a question but surely a work built upon a rather less grandiose scale than this one would have offered far more hope of capturing the attention of practising earth scientists and of turning them momentarily aside from their electron microprobes and X-ray diffractometers.

Rudwick concludes his story at the somewhat unsuccessful Cork meeting of the British Association held in August 1843, but an Irish geologist must observe that had Rudwick chosen to linger awhile amidst the rocks of southern Ireland he might have added one final twist to his tale. In the 1860s Professor J. B. Jukes, the Director of the Geological Survey of Ireland, became convinced that in southern Ireland he had discovered a unique key to the rocks of Devon and he sought to have re-opened the entire Devonian issue. Jukes was one of the finest field geologists of his generation but his one-man campaign had achieved little by the dawn of the day in early May 1869 when he found himself committed to a Dublin lunatic asylum. There Jukes died two months later. That bizarre little episode now awaits the attention of some scholar eager to erect an outhouse to the rear of Rudwick's splendid Gothicedifice. □

The trouble with book making

Colin Patterson

Oxford Surveys in Evolutionary Biology. Volume 1: 1984. Edited by R. Dawkins and M. Ridley. *Oxford University Press: 1984 (1985).* Pp. 227. £25.

THIS is an enigmatic publication. Though it looks like a book, with hard cover and dust jacket, it is the first issue of a new serial. Though new, the only introductory or explanatory matter lists a 15-strong editorial board which does not include one of the two editors. Though edited and published in Oxford, UK, all 11 contributors are American.

Given no introduction or policy statement, the reader must reconstruct the aims and scope of the *Surveys* from the contents, seven papers and a book review supplement. The papers are: J. T. Bonner on chemical signal-receptor systems; Lynn Margulis and Dorion Sagan on the origins of sex and its maintenance not as adaptation but as "imperative relic"; J. E. Lloyd on deception in nature, particularly in firefly flashing; D. H. Janzen on sphingids and saturniids as alternative ways of being a big moth; O. T. and D. J. Solbrig on plant growth hierarchies and fitness; M. T. Clegg on multilocus population genetic theory and practice; and Niles Eldredge and S. N. Salthe on hierarchy and evolution, a shot at outlining a theory more complete than neo-Darwinism. Finally, M. T. Ghiselin reviews "nine books of cladism" — "on" is intended here, and the books reach back to the 1970s, though one might miss the fact since the publication date of the oldest is omitted.

Of course, that last comment is carping over trivia, but misprint, anachronism and omission are unfortunately typical of the slapdash production of this book. For example, mismatches between text citations and bibliographies are rife — in one paper 26 per cent of the references mentioned in the text are inconsistent with the bibliography. The same bibliography contains 1985 publications along with 1983 papers cited only as "in press", without title or journal. And Daniel Janzen's fascinating essay is marred by execrable printing of the four colour plates.

At 55 pages Janzen's paper is the longest and has the strongest empirical content of any in the book, but that content is not to be retrieved from the index, which is formed on some idiosyncratic principle by which certain papers are indexed in excruciating detail, but Janzen's is found under only three headings (the name of the Costa Rican park where the work was done and the names of the two moth families, one of which is misspelled). While the general tone of most of

the papers is panslectionist, or organismic rather than molecular, the index gives precisely equal space to genetic drift and natural selection, one page reference each. In short, the index is untrustworthy and so useless.

But what about the papers? Well, they vary greatly in what they demand of the reader; some are original; most are conspicuously well written. I hope that others may appreciate their quality without the mounting irritation over production faults that spoiled my reading. If this new serial is to make itself a niche among the journals and the various *Annual Reviews* that cover the burgeoning field of evolutionary biology, someone will have to take a lot more trouble over it. □

On scale

E. J. Aiton

Measuring the Universe: Cosmic Dimensions from Aristarchus to Halley. By Albert Van Helden. *University of Chicago Press: 1985.* Pp. 203. \$30, £27.50.

ALTHOUGH the generally accepted scheme of planetary distances remained virtually unchanged throughout the Middle Ages and up to the time of Copernicus, it is only within the past 20 years that Ptolemy has been shown to have been its author. Following a surmise of Willy Hartner that the planetary distances were contained in a missing part of Book II of Ptolemy's *Planetary Hypotheses*, Bernard Goldstein located the scheme in a section of an Arabic version of Book I which has not survived in Greek.

The story of man's endeavours to assess the scale of the Universe goes back to the third century BC and the attempts of Aristarchus to measure the sizes and distances of the Sun and the Moon. His methods of lunar dichotomy and eclipse observations, though mathematically sound, depended on an accuracy of measurement which is impossible to achieve even today. As for the distances of the planets and stars, Ptolemy, writing in the second century AD, could only appeal to a system of space-filling spheres that could accommodate his eccentrics and epicycles.

In his study of the evolution of thought on cosmic dimensions, Albert Van Helden offers a clear and informative analysis of the sources and also the findings of modern scholarship relating to an important aspect of astronomy which has not hitherto been the subject of a separate monograph. He sees the invention of the telescope as a turning point in the path leading from the philosophically based scheme of Ptolemy to the determination

of reasonably accurate measured distances and sizes in the latter part of the seventeenth century.

The system of Copernicus not only permitted the deduction of the relative distances of the planets from the geometrical models but also revealed gaps between the spheres. Kepler explained the gaps by means of his polyhedral hypothesis and constructed a harmonic theory of the relative distances which agreed remarkably well with the empirical results based on Tycho's observations and his own planetary laws. Kepler broke with tradition in greatly enlarging the solar distance, though he kept it as small as possible; his analysis of the parallax of Mars and his calculations of eclipses had convinced him that the solar parallax could not exceed 1'. By adopting this value, he still underestimated the absolute size of the planetary system by a factor of about six. While the telescope had brought the possibility of determining the apparent diameters of the planets, the poor optical quality and the technical difficulties of observing prevented accurate measurements, so that Kepler had to combine harmonic hypotheses with observations in his derivation of their sizes. Soon after Kepler's death, the seemingly paradoxical smallness of Mercury revealed by observations of the transit in 1631 demonstrated the need for a new set of apparent diameters based entirely on telescopic measurements.

Accurate determination of the planetary distances and sizes was eventually achieved through the application of new technical inventions, namely the micrometer and telescopic sight, a better understanding of refraction and improved solar theory. Prominent among the astronomers who pursued these investigations were Flamsteed in England and Cassini in France. The popular view of historians and astronomers that the first successful measurement of the parallax of Mars (and hence of the solar parallax) resulted from the simultaneous observations made by Cassini in Paris and Richer in Cayenne in 1672 is contested by Van Helden, who explains that the error margin was too high to justify great confidence in the results obtained. Though producing values fortuitously close to those accepted today, the method employed was severely criticized by Halley, who advised that, for an accurate determination of the solar distance, astronomers would have to await the transit of Venus in the next century. Nevertheless, the publication by Flamsteed and Cassini in 1673 of a value for the solar parallax of 9.5" or 10" (equivalent to a solar distance of about 88 million miles) is seen by Van Helden as a watershed in the measurement of the cosmic dimensions. □

Business of biology

Renton Righelato

Reshaping Life: Key Issues in Genetic Engineering. By G. J. V. Nossal. Cambridge University Press: 1985. Pp.158. Pbk £6.95, \$11.95.

Setting Genes to Work: The Industrial Era of Biotechnology. By Stephanie Yanchinski. Viking: 1985. Pp.157. £12.95.

The Gene Factory: Inside the Biotechnology Business. By John Elkington. Century, London: 1985. Pp.240. £12.95.

"WHEN historians look back on the twentieth century they will conclude that its first half was shaped by the physical sciences but its second by biology." So begins one of these three new popular books describing industrial biotechnology and the potential benefits of the applications of molecular biology. All three are short, easy to read and suitable for the educated layman and scientists outside the subject

ing this growing technological power; the author concludes that there is adequate awareness of risks in both the scientific community and the public at large, and that the existing legislative and voluntary frameworks for control are satisfactory. Nossal's particular achievement in this book is that he succeeds in being at once sound and visionary.

The other two books both deal with the commercial development of biotechnology and both are by journalists. In *Setting Genes to Work* Stephanie Yanchinski describes, in an easy style, an industrial revolution based on microbes. She touches lightly on the applications, the companies and the people involved in some of the glamorous uses of biotechnology, largely in medicine, but also in food, agriculture and even computing (a DNA-coded, self-assembling biological computer).

John Elkington, the editor of *Biotechnology Bulletin*, reviews the growth of industrial biotechnology from the late 1960s to the end of 1984. He pieces together short notes from interviews and press re-

Milestones in the commercial development of biotechnology*

- | | |
|--|---|
| 1973: First gene cloned. | approved for use in the USA; initial public offering by Cetus sets Wall Street record for the largest amount of money raised in an initial public offering (\$125 million). |
| 1974: First expression of a gene cloned from a different species in bacteria. | |
| 1975: First hybridoma created. | |
| 1976: First firm to exploit recombinant DNA (rDNA) technology founded in the USA (Genentech). | 1982: First rDNA animal vaccine (for colibacillosis) approved for use in Europe; first rDNA pharmaceutical product (human insulin) approved for use in the USA and UK. |
| 1978: First product made with rDNA (somatostatin). | |
| 1980: <i>Diamond v. Chakrabarty</i> —US Supreme Court rules that microorganisms can be patented under existing law; initial public offering by Genentech sets Wall Street record for fastest price per share increase. | 1983: First plant gene expressed in a plant of a different species. |
| 1981: First monoclonal antibody diagnostic kits | 1984: Judge John Sirica thwarts the scheduled environmental release of rDNA organisms; Stanford awarded Cohen/Boyer patent on basic rDNA process. |

* Here abridged, the details are taken from Marc Lappé's *Broken Code: The Exploitation of DNA*, recently published by Sierra Club Books, San Francisco, price \$17.95. The original source was *Commercial Recombinant DNA: An International Analysis*, produced by the Office of Technology Assessment, January 1984.

areas directly involved. The authors each succeed in being up to date, but the subject is changing so rapidly that one feels that each volume should bear a "read by" date.

The least ephemeral of the books is Dr Nossal's, *Reshaping Life*, whose introduction I quote above. He goes on to explain simply, but accurately, the key features of molecular and cell biology, and exemplifies their practical application. These early chapters on cellular organization and the genetic code can be skipped by those with a basic biological training.

There follows a discussion of a number of actual achievements and exciting potential uses, among them genetically engineered proteins for correction of metabolic disorders and new vaccines, gene therapy and gene probes in diagnosis — developments which will fundamentally effect the quality of life and longevity. Whilst health-care applications dominate, there is a section on the uses of genetic engineering in agriculture and the food industry, and another describing the growth of biotechnology companies. Two chapters give a balanced discussion of the ethical and public-policy issues surround-

ports with accounts of most of the British, and many of the American, companies involved in bringing in the newer products which depend on genetic engineering and other aspects of biotechnology. Accuracy is sometimes sacrificed to style, but as a catalogue of commercial developments it is readable and reasonably comprehensive: over 200 companies are mentioned, concerned with the applications of biotechnology in medicine, agriculture, animal breeding and food production.

In both Yanchinski's and Elkington's books I would have liked a more critical analysis, perhaps through case studies, of the business and technical factors which have made ventures succeed or fail. But, perhaps we should be grateful that those with the scientific and commercial acumen to write such a book are too busy with their demanding task of developing the products and building the new businesses on which the reality of our much-heralded revolution depends. □

Never ending circuits

Peter Beverley & Andrew McMichael

The Biology of Idiotypes. Edited by Mark I. Greene and Alfred Nisonoff. Plenum: 1984. Pp.507. \$59.50, £56.53.

Idiotypy in Biology and Medicine. Edited by Heinz Köhler, Jacques Urbain and Pierre-André Cazenave. Academic: 1985. Pp.445. \$78, £78.

It is more than twenty years since immunoglobulin idiotypes were first described by Oudin and Kunkel, and more than ten since Niels Jerne proposed his theory of an idiotypic-based immunoregulatory network. The recent award of a Nobel prize to Jerne is a recognition of the importance of his contribution, though many of the key observations were made before he proposed his theory and before the modern techniques of protein chemistry and molecular genetics became available.

After the initial description of specific antigenic determinants (idiotypes) present on antibody molecules raised against bacterial antigens, it was shown that the same idiotypes could also be detected on immunoglobulin unreactive with the immunogen. In addition idiotypes were shown to be under genetic control. None of this linked idiotypes to immunoregulation but the network theory soon did so. Supporting experimental evidence rapidly appeared, perhaps the earliest being the observation that (auto) anti-idiotypic is produced during the course of a normal immune response. This theoretical and experimental base stimulated an enormous number of experiments which are the subject of the two books reviewed here. Two major topics are covered: the structural basis of idiotypes, and their role in regulation of immune responses in health and disease. The more practical question of whether anti-idiotypic responses can be used to control aberrant immune responses underlies much of the thinking. None of these issues has yet been resolved but the attempts to do so

make interesting and instructive reading.

Of the two books, *The Biology of Idiotypes* is the more biochemical, and *Idiotypy in Biology and Medicine* is more concerned with networks and their role in disease. There is, however, considerable overlap between them, with several authors contributing to both.

The first half of *The Biology of Idiotypes* is devoted to the molecular, genetic and structural aspects of idiotypes, with several chapters presenting data on the expression of private and cross-reacting idiotypes on families of antibodies reacting with a simple, structurally defined antigen. These chapters illustrate the power of the hybridoma method for producing antibodies of defined specificity in mice of any desired genetic makeup, whereas previous work on the structural basis of idiotypy relied upon myeloma paraproteins, often of unknown antigen specificity and uncontrolled genetic origin. Nevertheless, in spite of the sequence data on families of related, defined-antigen-binding, monoclonal antibodies, there are still very few examples where a particular amino acid residue can be definitively associated with expression of an idiotypic determinant. (A new and intriguing example was described recently by Radbruch *et al.* in *Nature* 315, 507 (1985), where an amino acid change in the diversity (D) segment of the antibody led to loss of idiotypy but not antigen specificity.) The reasons for this are made clear. Most antibodies, including anti-idiotypes, react with conformational determinants made up of amino acids which may be widely separated in terms of primary sequence. From the genetic point of view analysis is complicated by the observation that contributing to variability are not only variable region (V) genes, but also D and joining region (J) minigenes, as well as infidelity of VDJ assembly and somatic mutation. All of these issues are extensively and well discussed, as is the limited amount of information on the three-dimensional structure of immunoglobulin molecules, which, combined with sequence analysis, may ultimately hold the key to understanding the structural basis of idiotypes.

The second half of *The Biology of Idiotypes* and most of *Idiotypy in Biology and Medicine* deals with the regulation of idiotypes. The network theory itself is particularly well discussed in the latter book, by Köhler, and there are detailed accounts of experiments designed to test its validity. These sections are very much for cellular immunologists, covering cell transfer experiments, separation of T and B cells, induction of help and suppression and experimental immune diseases. Many of the experiments described exemplify the powerful effects which administration of idiotypes or anti-idiotypes can have on subsequent immune responses.

The problem with these chapters is that they have been overtaken by events of the

past two years. Several contributors were wrestling with the difficulty of integrating T and B cells into a coherent network at a time when the T cell receptor had not been characterized. The ease with which T-cell idiotypes have subsequently been detected by monoclonal antibodies, and the general similarity of the T-cell receptor chains to immunoglobulin light chains, now make an integrated network much more credible. However, it is still not clear that T-cell receptors can respond to idiotypes on B cells or other T cells. In Köhler's reiteration of Jerne's view, the T-cell repertoire may be selected and expanded by the images of B-cell antibody receptors presented with self-antigen of major histocompatibility complex (MHC). This neatly explains the apparent genetic linkage between the two, a finding that can now be tested with much greater rigour.

Another question is whether or how to fit in antigen processing. Although not universally accepted, there is considerable evidence that helper T cells respond to processed (fragmented) antigens plus MHC Class II antigens. Are they able therefore to recognize idiotypic processed and presented on T or B cells in a manner similar to other antigens? Although not known for T cells, B cells can clearly present foreign antigen. But are the rules different for self idiotypes (and allo-MHC antigens)? Should we be looking for idiotypic determinants which are the same as those seen by B cells, or at short, linear amino acid sequences presented with the self-MHC antigen?

Further, there is another layer of complexity: the antigens could select the T cells in a positive fashion; it is known that the antibody to the T-cell antigen receptor can stimulate T-cell division, as can antibody to the associated CD3 glycoprotein. One experiment, described by Greene *et al.* in *Idiotypy in Biology and Medicine*, indicates that a B-cell hybridoma secreting anti-idiotypic specific for anti-reovirus $\sigma 1$ glycoprotein is killed by cytotoxic T cells specific for the same antigen. We need to know who recognizes whom.

These issues can now all be addressed and the appropriate experiments are surely in progress. For many readers, ultimate proof of the network hypothesis will depend upon clear understanding of the interactions between the receptors of T and B cells and between those of the T cell subsets. The two books contain many interesting data and ideas, and can be thoroughly recommended to those who wish to prepare themselves for these impending and, we can hope, conclusive advances. □

Limiting and realizable efficiencies of solar photolysis of water

James R. Bolton*, Stewart J. Strickler† & John S. Connolly‡

* Photochemistry Unit, Department of Chemistry, University of Western Ontario, London, Ontario, Canada N6A 5B7

† Department of Chemistry, University of Colorado, Boulder, Colorado 80309, USA

‡ Photoconversion Research Branch, Solar Energy Research Institute, 1617 Cole Boulevard, Golden, Colorado 80401, USA

A critical analysis of various schemes for the solar photolysis of water into hydrogen and oxygen places ideal limits on their efficiencies. Single-bandgap schemes will have practical efficiencies of up to 10%, but the prospects of higher efficiencies from dual-bandgap schemes are encouraging.

OF the many reactions proposed for solar generation of energy-rich reduced molecules (fuels) using common reagents such as water, carbon dioxide and nitrogen¹, none has gained as much attention as the solar photolysis of water

Because water is transparent to virtually all of the solar spectrum, sensitizers must be used if sunlight is to drive the reaction. Heidt² first reported a complete water-photolysis reaction; in his system the reaction was sensitized in low yields by Ce^{4+} and Ce^{3+} using ultraviolet light. Fujishima and Honda³ later reported the first complete photoelectrolysis of water at semiconductor electrodes. Since then, many sensitizers and water-decomposition systems have been studied (see refs 1, 4–20 for reviews).

In the light of recent interest in the reaction, it is important to examine limits on its efficiency and, further, to estimate efficiencies that might be achieved based on realistic assumptions. This problem was examined in 1978 (ref. 1) in the general context of solar fuel-generation reactions. Here, we update this study and specifically analyse the water-photolysis reaction.

Classification of reaction schemes

Balzani *et al.*⁸ were the first to present an extensive analysis of various schemes for solar water decomposition. They proposed four cycles, C1–C4, to classify various reaction schemes based on photosensitized processes with successively lower threshold energies needed to initiate the photochemical step. In the C1 and C4 cycles, two photons are required to split one H_2O molecule, whereas in the C2 and C3 cycles one photon per H_2O is required. Only the C3 and C4 cycles lead to formation of molecular H_2 and O_2 . This classification was later adopted by Bolton¹, who added a C5 cycle which involves two photosystems operating at the same threshold wavelength to drive the oxidation and reduction steps, respectively; in this scheme four photons are required to split one H_2O molecule into H_2 and O_2 . Here we have chosen a simpler and broader classification.

There are two critical factors in evaluating schemes for the photolysis reaction: (1) the number of photosystems used to carry out the photochemical process (we consider here mainly schemes using a single (S) photosystem or using dual (D) photosystems with different threshold wavelengths and placed one behind the other); (2) the number of photons used for each hydrogen molecule evolved (we consider the use of 1, 2 or 4 photons). The possible schemes are accordingly denoted S1, S2, S4, D2 and D4 (Table 1).

Ideal limits on efficiencies

Several authors have treated the general problem of ideal limits on conversion of solar energy into useful work or stored chemical energy^{21–28} and there is now general agreement on the significance of these limits on direct solar energy conversion processes. Briefly, three basic approaches have been taken: (1) Shockley

and Queisser²¹ developed the concept of the ideal photovoltaic cell and demonstrated that the maximum conversion efficiency is ~31% in AM0 sunlight. (The intensity of sunlight is reduced by passage through the atmosphere, and the amount of air traversed is an important parameter. Air Mass one (AM1) corresponds to sunlight having passed vertically through the atmosphere to sea level. AM0 refers to sunlight above the atmosphere and AM1.5 to light coming at such an angle (~48° from the vertical) that it has traversed 1.5 times as much air as AM1 radiation.) (2) Ross^{22,23} and Ross and Calvin²⁴ generalized the Shockley and Queisser treatment to all photochemical solar energy conversion processes. Ross and Hsiao²⁵ treated the problem further using a chemical thermodynamic approach and also obtained an ideal efficiency limit of ~31%. (3) Haught²⁶ developed a general analysis based on Planck's and Kirchhoff's laws, and also obtained an ideal limit efficiency of ~31%.

Bolton, Haught and Ross²⁷ then showed that these three approaches are, in fact, equivalent. Porter²⁸ has recently presented a parallel analysis of the problem from the standpoint of successive efficiency losses. We have performed our calculations within the framework of the Ross treatment^{22–27}.

The essential features of the model are as follows: light is absorbed by a material (for example, a semiconductor or a molecular ensemble) having a certain excited-state energy U_g with a corresponding bandgap or threshold wavelength λ_g . Photons of longer wavelength are not absorbed; those of wavelengths shorter than λ_g may be absorbed, but thermal equilibration of the excited state with the surroundings usually occurs very rapidly so that the system relaxes to an energy close

Table 1 Classification system for solar water photolysis schemes

Scheme classification	No. of photo-systems	Minimum no of absorbed photons per H_2	Reaction
S1	1	1	$\text{H}_2\text{O} \xrightarrow{1h\nu} \text{H}_2 + \frac{1}{2}\text{O}_2$
S2	1	2	$\text{H}_2\text{O} \xrightarrow{2h\nu} \text{H}_2 + \frac{1}{2}\text{O}_2$
S4	1	4	$\text{H}_2\text{O} \xrightarrow{4h\nu} \text{H}_2 + \frac{1}{2}\text{O}_2$
D2	2	2	$\text{H}_2\text{O} \xrightarrow{h\nu_1 + h\nu_2} \text{H}_2 + \frac{1}{2}\text{O}_2$
D4	2	4	$\text{H}_2\text{O} \xrightarrow{2h\nu_1 + 2h\nu_2} \text{H}_2 + \frac{1}{2}\text{O}_2$

S, single photosystem; D, dual photosystems operating at different threshold wavelengths λ_1 and λ_2 . Scheme classification can be generalized to the solar production of any reduced fuel by taking the number in column 3 to specify the minimum number of photons required to generate the reducing equivalent of one H_2 molecule.

to U_g within a time <10 ps. We note that, under certain conditions, it is possible that thermal equilibration of the excited states is not achieved before electron transfer occurs; 'hot carrier' effects could, conceivably, then enhance the ideal limiting efficiencies²⁹.

In agreement with the requirements of microscopic reversibility, the excited state can radiate; this limits the concentration of excited states or minority carriers that can be built up. If electrical power or chemical products are to be extracted, there will necessarily be a further reduction in excited-state concentration. The model predicts that the efficiency of conversion of incident solar energy to chemical (Gibbs) energy is limited to

$$\eta = \frac{J_g \cdot \mu_{ex} \cdot \phi_{conv}}{S} \quad (2)$$

where J_g is the absorbed photon-flux (photons $s^{-1} m^{-2}$) for solar wavelengths such that $\lambda \leq \lambda_g$; μ_{ex} is the excess chemical potential generated in the system by absorption of light; ϕ_{conv} is the quantum yield for conversion of absorbed photons into products and S is the total incident solar irradiance ($W m^{-2}$). ($\phi_{conv} = 1.0$ means that every absorbed photon is 100% effective in generating products. Thus, in terms of the classification scheme used here, the corresponding quantum yields of H_2 formation would be 1.0 for S1, 0.5 for S2 or D2 and 0.25 for S4 or D4 systems.) The quantities μ_{ex} and ϕ_{conv} are not independent; the highest values of μ_{ex} can be achieved only for small ϕ_{conv} and vice versa. The Ross treatment²²⁻²⁷ allows optimization of these parameters to give an ideal maximum efficiency η_p for any given λ_g . (Strictly speaking, η_p is not a thermodynamic limit in that it is defined for a condition of maximum power and not for a reversible process.)

For an ideal chemical system^{25,27} with-negligible depletion of the ground state

$$\mu_{ex} = \mu_{light} - \mu_{dark} = kT \ln \left(\frac{x_{A^*}}{x_{A^*}^{eq}} \right) \quad (3)$$

where μ_{light} and μ_{dark} are the chemical potentials of A^* in the light and dark, respectively; x_{A^*} is the mole fraction of excited states A^* present at steady state under solar irradiation; and $x_{A^*}^{eq}$ is the corresponding mole fraction present at equilibrium in the dark at absorber temperature T (taken as 300 K). An important concept in the Ross treatment is that there is always a certain fraction of U_g which is unavailable to do work. We term the unused energy per photon U_{loss} , defined by

$$U_{loss} = U_g - \mu_{prod} \quad (4)$$

where μ_{prod} is the chemical potential of the products. Ross has pointed out that the upper limit of μ_{prod} is μ_{ex} , and showed that the optimum efficiency is achieved with $U_{loss} \sim 0.3-0.4$ eV, the exact value depending on λ_g . Details of these calculations are described elsewhere^{25,27}.

To account for losses in the production of solar fuels by real systems, Bolton¹ introduced the factor η_c , which is the overall efficiency of conversion of solar energy to stored chemical energy

$$\eta_c = \eta_g \eta_{chem} \phi_{conv} \quad (5)$$

where η_g is the fraction of incident solar irradiance that is converted to energy of the lowest excited state of the absorber

$$\eta_g = \frac{J_g U_g}{S} \quad (6)$$

η_{chem} is the fraction the excited-state energy converted to stored chemical energy and is defined by

$$\eta_{chem} = \frac{\Delta G^\circ/n}{U_g} = \frac{U_g - U_{loss}}{U_g} \quad (7)$$

and ϕ_{conv} is the quantum efficiency of the fuel-forming reaction. In equation (7) ΔG° is the standard Gibbs energy and n is the number of photons used to drive the reaction as written. In real systems, U_{loss} will be greater than the ideal value of $\sim 0.3-0.4$ eV (ref. 27); the actual value will be determined by the degree to

Fig. 1 Spectral distribution of the solar photon flux based on the AM1.5 global data of Bird *et al.*³².

which any real system approaches the ideal limit. In principle, the quantum efficiency factor ϕ_{conv} in equation (5) can be made very close to unity for real systems and is ~ 0.98 for the 'ideal' case²⁷. A major goal of practical systems is to achieve ϕ_{conv} close to unity.

Because the reactions we are considering are endergonic, the entire ΔG° must be obtained from photon energy. Hence, for a given reaction and U_{loss} there will be a threshold wavelength λ_t which is just capable of driving the reaction; specifically as shown by Bolton, Haught and Ross²⁷

$$\lambda_t = \frac{hc}{[\Delta G^\circ/n + U_{loss}]} \quad (8)$$

where h is Planck's constant and c is the speed of light.

Absorbed photon flux

We have shown in equations (2) and (6) that J_g is an important quantity in solar efficiency calculations. J_g is defined by²⁷

$$J_g = \int_0^{\lambda_g} J_\lambda \alpha(\lambda) d\lambda \quad (9)$$

where $\alpha(\lambda)d\lambda$ is the fraction of incident radiation absorbed in the wavelength band from λ to $\lambda + d\lambda$, and J_λ is the corresponding incident spectral solar photon flux (photons $m^{-2} s^{-1} nm^{-1}$). The solar spectrum is conventionally measured as a spectral irradiance E_λ ($W m^{-2} nm^{-1}$) which is related to J_λ by

$$J_\lambda = \frac{E_\lambda \lambda}{hc} \quad (10)$$

The choice of an appropriate solar spectral distribution is an important consideration as it is known³⁰ that such distributions vary considerably with changes in atmospheric conditions. However, Buhl *et al.*³¹ have recently shown that if one chooses a 'global' distribution (that is, one including light from all angles incident on a surface) rather than a 'direct beam' distribution, the calculated ideal efficiencies do not vary much with changes in atmospheric conditions (for example, turbidity, water vapour and ozone concentrations) or even air mass. (Global distributions are appropriate for flat-plate collectors, whereas direct-beam distributions are appropriate for concentrating collectors since the diffuse component cannot be concentrated.) Thus, we have chosen to use the unconcentrated, global AM1.5 spectral irradiance distribution developed by Bird *et al.*³², probably the best data currently available. (A printout of I_λ , J_λ and the integrated photon flux J_g for $\lambda \leq \lambda_g$ is available from any of the authors.) A plot of J_λ against λ is shown in Fig. 1.

Analysis of limits

Considered as an oxidation-reduction process, reaction (1) involves a two-electron transfer with a standard cell potential of 1.229 V. Thus, for S1 schemes, 2.458 eV Gibbs energy must be supplied per photon. S2 or D2 schemes require an average of 1.229 eV per photon and S4 or D4 schemes only 0.615 eV per photon. In the following discussion we divide our analysis

Fig. 2 Efficiencies for conversion of solar radiation to stored Gibbs energy using single-bandgap devices. The full curve shows η_p , the ideal limiting efficiency. The vertical lines at 420, 775 and 1,340 nm show the maximum threshold wavelengths for reaction (1) carried out by S1, S2 and S4 schemes, respectively, under ideal conditions. The descending curves through the dots show the changes in efficiencies and bandgap wavelengths for values of U_{loss} greater than the optimum; the numbers at the dots are the respective values of U_{loss} in eV per photon at those points.

according to whether the sunlight is absorbed in a photosystem with a single bandgap (S) or in a system with dual bandgaps (D). **Single-bandgap systems.** The upper curve in Fig. 2 shows a plot of the ideal limiting efficiency, η_p , against the bandgap wavelength λ_g for the AM1.5 global solar distribution. Similar curves have been calculated for other terrestrial distributions^{1,27,31}. η_p rises sharply in the range 400–800 nm primarily because J_g increases rapidly in this region. However, as λ_g increases, the available Gibbs energy per photon decreases; for $\lambda_g > 1,100$ nm this causes η_p to decrease. The curve in Fig. 2 shows the ideal limit on the efficiency of any single-bandgap device for direct (that is, quantum) conversion of unconcentrated sunlight to chemical or electrical energy. If the respective optimum values of U_{loss} are inserted into equation (8), it is possible to calculate the 'ideal' values of λ_t for S1, S2, or S4 water-photolysis schemes. These wavelengths are indicated in Fig. 2 by vertical lines along with the corresponding values of U_{loss} . It is clear from the figure that S1 schemes can be removed from further consideration for practical systems because even the 'ideal' maximum efficiency for an S1 system is only ~5%. Thus, the remainder of the analysis in this section deals only with the S2 and S4 cases.

We first consider S2 systems. In accord with Fig. 2, the ideal maximum efficiency for the S2 case is 30.7% at $\lambda_g = 775$ nm.

(This analysis is based on the standard potential of reaction (1) which assumes that the product gases are produced at 1 atm pressure and at 298 K. If the products are produced at a lower pressure, the Gibbs-energy requirement will be reduced and the threshold wavelength will shift to the red. For example, at a pressure of 10^{-3} atm hydrogen, the potential of the reaction is only 1.052 V; from equation (8), $\lambda_t = 880$ nm, and the apparent maximum efficiency could increase to 33.3%. Of course, if the hydrogen produced must be compressed to ≥ 1 atm, work will have to be expended, so the gain in efficiency obtained by using a longer wavelength threshold could not be fully realized.) Under these ideal conditions, U_{loss} has the optimum value of 0.37 eV. Solar conversion efficiencies for water photolysis under various conditions are collected in Table 2.

It is worthwhile to consider briefly the physical meaning of the various energy losses in a photochemical system. The ideal S2 system would require the use of molecules with excited-state energy $U_g = 1.60$ eV ($\lambda_g \approx 775$ nm); photons with shorter wavelengths will produce excited states of higher energy, but these will relax very quickly to U_g with dissipation of any extra energy into heat. To a good approximation, we can regard 1.60 eV as the standard chemical potential of the excited state relative to that of the ground state. But the concentration of the excited state will be much less than that of the ground state, so its actual chemical potential relative to the ground state, given by equation (3), will be lower than the standard value. Under optimum conditions, it will be lower by 0.37 eV, giving a value of $\mu_{\text{ex}} = 1.23$ eV, just enough to drive reaction (1) if there are no additional losses. The energy difference $U_{\text{loss}} = 0.37$ eV is required to be delivered as additional heat to the surroundings when the excited states are returned to the ground state in the process of extracting work to carry out the chemical reaction. The complete derivation of the optimum U_{loss} will be found in earlier literature^{1,27}.

Real systems clearly will involve U_{loss} greater than the ideal value. For example, in a photoelectrochemical cell the electrode polarization (or overvoltage) will contribute to U_{loss} , as this term must include all polarization losses, even those at a dark electrode. Figure 2 also shows what happens to the efficiency and λ_t as we assume various larger values of U_{loss} . We feel that a reasonable goal for an operating system would be $U_{\text{loss}} \sim 0.8$ eV, in which case the efficiency could be no more than ~17% at $\lambda_t \sim 610$ nm. As U_{loss} increases beyond this value, the attainable efficiency drops very rapidly (Fig. 2, Table 2). This results primarily from the fact that as λ_t shifts to the blue, the fraction of the solar photon flux absorbed drops very rapidly. Therefore, we conclude that S2 schemes will require sensitizers with $\lambda_g < 610$ nm (or semiconductors with a bandgap of > 2.0 eV) to drive reaction (1). Also, the system will have to be very carefully designed to minimize all contributions to U_{loss} .

The major problem with S2 systems is that they are limited to rather short threshold wavelengths, and, therefore, the absorbed solar photon flux is low. We now consider one way around this difficulty, the use of two photons to drive each

Table 2 Solar conversion efficiencies and other related data for solar photolysis of water using global AM1.5 solar radiation

Scheme	Conditions	η_p (%)	η_c (%)	U_{loss} per photon (eV)	Threshold wavelengths λ_t or λ_1 (nm)	λ_2 (nm)
S1	Ideal limit	5.3	—	0.49	420	—
S2	Ideal limit	30.7	—	0.37	775	—
S2	Chemical conversion	—	23.5	0.60	680	—
S2	Chemical conversion	—	17.4	0.80	610	—
S2	Chemical conversion	—	12.7	1.00	555	—
S4	Ideal limit	30.6	—	0.31	1,340	—
D2	Ideal limit	42.4	—	0.38*	655	930
D4	Ideal limit	41.0	—	0.31*	910	2,610
D4	Chemical conversion	—	32.3	0.60	785	1,465
D4	Chemical conversion	—	27.1	0.80	720	1,120
D4	Chemical conversion	—	21.6	1.00	655	925

In schemes D2 and D4, it is assumed that equal photon fluxes are used by the two photosystems.

* Average U_{loss} per photon.

Fig. 3 Contour diagram showing the ideal limiting efficiencies (η_p , %) in a layered dual-bandgap system with bandgap wavelengths λ_1 and λ_2 . Dashed line, path of equal effective photon fluxes used in two photosystems as required for use of the two halves in series.

electron in the reaction, or four photons per H_2 molecule produced. Less energy is required from each photon, a longer threshold wavelength is possible, and so more photons can be absorbed. As indicated in Fig. 2 and Table 2, the ideal S4 case occurs with $\lambda_1 = 1,340$ nm and $U_{\text{loss}} = 0.31$ eV. The ideal maximum efficiency is $\sim 30.6\%$, virtually the same as in the S2 case. However, as U_{loss} is increased above the ideal value, the efficiency does not drop quite as rapidly for the S4 system, and at $U_{\text{loss}} = 0.8$ eV per photon the efficiency would be $\sim 19\%$ (Fig. 2).

Dual-bandgap systems. The dilemma faced by a designer of a single-photosystem process is that if a high λ_g is used so as to absorb many photons, the energy available per photon is low, whereas if a low λ_g is used to give a high energy per photon, few photons can be absorbed. This suggests a scheme using two or more absorbing materials (or photosystems) with different bandgaps, placed one behind the other. The first, with bandgap wavelength λ_1 , is placed on top (that is, towards the Sun) and the other, with a longer bandgap wavelength λ_2 , is placed behind it to use photons not absorbed by the first. The first photosystem is assumed to absorb all photons with $\lambda \leq \lambda_1$, whereas the second absorbs all photons with $\lambda_1 < \lambda \leq \lambda_2$.

We first consider a case in which the two photosystems operate independently; each one is treated with the same equations used for a single photosystem with the respective bandgap and the proper number of photons absorbed. For each absorber we calculate the ideal maximum efficiency and then add the two values to get the total possible efficiency for the system. The results are displayed in Fig. 3 in the form of a contour diagram, showing the ideal limiting efficiencies as a function of the two bandgap wavelengths. Similar diagrams have been presented by Ross and Hsiao²⁵ and by Bolton¹. There is a considerable increase in the limiting efficiency compared with a single photosystem. The maximum solar efficiency (η_p) is $\sim 46\%$; this occurs when the top layer absorbs photons of wavelength shorter than ~ 720 nm and generates a chemical potential of ~ 1.34 eV, while the second layer absorbs the somewhat larger number of photons available with wavelengths between ~ 720 and $\sim 1,320$ nm and generates a chemical potential of ~ 0.61 eV. The two layers presumably would be used to drive two different uncoupled processes.

An alternative and attractive scheme for using two-layer systems is to couple the layers in series to increase the voltage in a photovoltaic device or the chemical potential in a photochemical or photoelectrochemical device. For example, in a photoelectrochemical cell the top layer might be a photoanode to produce O_2 from aqueous solution, while the back absorber would be a photocathode to produce H_2 . This permits the chemical potentials produced by the two sensitizers to combine

and drive a chemical reaction of higher energy than either material could drive alone. Such devices have the important additional restriction that each layer must use the same number of photons, that is, the number of photons absorbed multiplied by ϕ_{conv} must be the same for each layer. We use the optimum value of ϕ_{conv} for each system, which maximizes the energy stored^{1,22-25}. The restriction of equal numbers of photons used defines a relationship between the two bandgaps: essentially the number of photons with $\lambda \leq \lambda_1$ must equal the number with $\lambda_1 < \lambda \leq \lambda_2$, with a small correction for the different quantum yields required for maximum efficiency. This relationship then defines a path across the contour diagram of Fig. 3 as shown by the dashed line. Fortunately, the restriction of equal photon fluxes is not too serious, as the path follows quite closely the ridge of high efficiency across the diagram.

Figure 4 shows a similar contour diagram for solar efficiencies of dual-bandgap systems with an average U_{loss} of 0.8 eV per photon, which we take as a reasonable goal. (Even for larger U_{loss} values ϕ_{conv} can, in principle, be very close to unity. We have used $\phi_{\text{conv}} = 1.0$ to illustrate the maximum efficiencies for a given value of U_{loss} .) As in Fig. 3, the dashed line shows the path of equal photon fluxes absorbed in each layer. It is encouraging to note that this path still follows closely the ridge of high efficiency. The maximum efficiency on this diagram is $\sim 28\%$. The limits for water splitting are indicated and have efficiencies of ~ 24 and $\sim 27\%$ for D2 and D4 schemes, respectively.

Figure 5 presents data from these calculations in a manner which allows a comparison with Fig. 2. The top curve of Fig. 5 shows the ideal limiting efficiencies along the path of equal used photon fluxes plotted as a function of λ_2 ; this curve is the contour along the dashed line of Fig. 3. A few values of λ_1 are marked for reference. The two vertical lines show the respective threshold wavelengths for water splitting by D2 systems ($\lambda_1 = 655$; $\lambda_2 = 930$ nm) and by D4 systems ($\lambda_1 = 910$; $\lambda_2 = 2,610$ nm). Values of U_{loss} greater than the optimum values give a family of efficiency curves for η_c lying below the η_p curve. Three examples are shown with $U_{\text{loss}} = 0.6, 0.8$ and 1.0 eV.

By further analogy with Fig. 2, we also show in Fig. 5 lines representing the threshold wavelengths and efficiencies for water splitting when the energy losses per photon are larger than the ideal optimum values. As before, the threshold wavelength λ_2 shifts to the blue and efficiencies drop rapidly as larger losses are imposed. λ_1 also shifts to the blue; for example, in the D4 case with $U_{\text{loss}} = 0.8$ eV, $\lambda_1 = 720$ nm and $\lambda_2 = 1,120$ nm. Note, however, that because the ideal limiting efficiencies are rather

Fig. 4 Contour diagram showing efficiencies for layered dual-bandgap devices with U_{loss} taken as 0.8 eV per photon. By analogy with Fig. 3, the dashed line shows the path of equal photon fluxes absorbed in the two photosystems; the threshold wavelengths are indicated for carrying out reaction (1) with schemes D2 and D4, respectively.

Fig. 5 Conversion efficiencies for dual-bandgap devices with equal photon fluxes used in the two photosystems. By analogy with Fig. 2, the top curve shows the ideal limiting efficiencies (η_p), plotted as a function of λ_2 , with a few values of λ_1 indicated for reference. Vertical lines indicate maximum threshold wavelengths for reaction (1) carried out by schemes D2 and D4 under ideal conditions. Lower curves represent chemical conversion efficiencies η_c for $U_{\text{loss}} = 0.6, 0.8$ and 1.0 eV, respectively, assuming $\phi_{\text{conv}} = 1.0$ in each photosystem. Descending curves through the dots show the threshold wavelengths and efficiencies for U_{loss} greater than the respective ideal optimum values.

high for dual-bandgap systems, efficiencies can remain reasonable even when the losses are appreciable, and the λ_g values fall in the range of available sensitizers.

We emphasize that our analysis of D2 and D4 systems assumes that the second photosystem is placed behind the first to use those photons not absorbed by the first. One can also construct devices with two different photosystems placed side by side. The efficiency of such an arrangement can be analysed by treating each as a single photosystem and taking an area-weighted average of the two efficiencies. Because such systems offer little or no efficiency advantage over single photosystems, we will not analyse them further.

Examples

In this section we mention a few examples to illustrate the possibilities for solar energy conversion.

A photoelectrochemical cell using SrTiO_3 as a photoanode and a platinum cathode is capable of carrying out reaction (1) with a quantum yield of nearly unity³³⁻³⁵. However, U_g for SrTiO_3 is ~ 3.2 eV, so it absorbs only ultraviolet light and U_{loss} is ~ 2.0 eV. With this high value of U_{loss} , the solar efficiency is only $\sim 1\%$.

Grätzel^{11,12} and Lehn¹⁶ and their co-workers have reported success in producing both H_2 and O_2 in a photochemical system using trisbipyridyl ruthenium(II) as a sensitizer, methyl viologen as a charge relay and colloidal particles to catalyse the evolution of H_2 and O_2 . This sensitizer absorbs light at $\lambda \leq 500$ nm, so $U_{\text{loss}} = 1.2$ eV. If the quantum yield were high, this U_{loss} would allow an $\sim 8\%$ solar conversion efficiency. However, the quantum yield is itself only $\sim 5\%$, so if used as a solar converter, this system would have an actual efficiency well under 1% . In our analysis of limits, we have generally assumed the quantum yield to be high; this example serves to point out that this may not always be the case. One of the major tasks in designing practical systems is to devise ways to make the quantum yield approach unity. Both of the above cases are examples of S2 systems.

The Texas Instruments company has patented a system³⁶⁻³⁸ for splitting HBr rather than H_2O , using two sets of micro-spherical silicon photovoltaic arrays in series, with metal and metal oxide catalytic electrodes. This is not a true photoelectrochemical device but rather a tandem, photovoltaic-electrolysis system³⁹. The two sets of photovoltaic elements are slightly different but have the same λ_g , and are arranged side by side. The S4 analysis presented above applies to the system. Solar-to-chemical conversion efficiencies of ~ 4.5 – 5.5% have

been achieved for cell areas in the range of 100 – $1,000$ cm^2 (ref. 38). The bandgap energy of silicon is 1.1 eV, but it is an 'indirect bandgap' material, and the actual onset of absorption is probably ~ 950 nm in this device. For electrolysis of HBr to H_2 and Br_2 , this corresponds to $U_{\text{loss}} \sim 0.7$ eV per photon. We mention this system to point out that rather low values of U_{loss} are possible in S4 systems. However, it is relatively easy to achieve low U_{loss} values in splitting HBr because a platinum electrode can produce Br_2 at a low overpotential. In contrast, to carry out reaction (1) it is necessary to generate O_2 , which is generally difficult without suffering a large charge-transfer overpotential.

A fourth example is the reaction of green-plant photosynthesis:

This reaction has $E^\circ = 1.24$ V, virtually the same as reaction (1), so the considerations of efficiency are the same. Although the plant uses two somewhat different photosystems, they have nearly the same $\lambda_g \approx 690$ nm ($U_g \approx 1.80$ eV) and are intermixed in the leaf. Two photons are used to drive each electron, so even though no H_2 is generated, this system is also equivalent to the S4 case analysed above. Each photon must supply 0.62 eV to drive the reaction; hence $U_{\text{loss}} = 1.18$ eV and, from equations (5)–(7), the maximum conversion efficiency would be 12.4% if all light with $\lambda \leq 690$ nm were absorbed and used to drive reaction (11) with $\phi_{\text{conv}} = 1.0$. When real measured *in vivo* quantum yields and absorption coefficients (for example, in a leaf) are used, the gross efficiency drops to $\sim 9\%$ (refs 10, 40). Note, however, that if the photosynthesis reaction were to be driven by an S2 scheme with $U_{\text{loss}} = 1.18$ eV per photon, λ_1 could not be $> \sim 510$ nm and the maximum efficiency would be only $\sim 9\%$.

As a final example, we note that several investigators have studied photoelectrochemical cells with a photoanode and a photocathode in series, using different semiconductors for the two photoelectrodes⁴¹⁻⁴³. For example, a cell with a photoanode of n-TiO₂ ($\lambda_g \approx 410$ nm) and a photocathode of p-GaP ($\lambda_g \approx 550$ nm) will split water, although the efficiencies achieved have been rather low. These experiments were performed with the electrodes side by side, but in principle the GaP electrode could be placed behind the TiO₂ electrode, and this would be an example of a D4 system. The two bandgaps are not well matched for equal absorbed photon fluxes, and $U_{\text{loss}} \approx 2.0$ eV in this example, so it serves mainly to show that the concept of such D4 systems is workable. However, there are practical difficulties with layered systems, such as providing transparent ohmic contacts.

Realizable efficiencies

Up to this point the only non-ideal factor we have considered is an increase in U_{loss} . We concluded that $U_{\text{loss}} \approx 0.8$ eV is a realistic goal for a practical system, which leads to calculated maximum efficiencies of $\sim 17\%$ ($\lambda_1 \approx 610$ nm) for S2 systems and $\sim 27\%$ ($\lambda_1 \approx 720$; $\lambda_2 \approx 1,120$ nm) for D4 systems. In practical devices, however, there are other losses to be considered: (1) Reflection losses. The collector in which the photochemical reaction occurs must have a transparent cover. Each surface through which the sunlight passes results in a reflection loss of ~ 4 – 5% for untreated glass at normal incidence and considerably more at higher angles of incidence⁴⁴. These losses can be reduced with anti-reflection coatings, but at added cost. We shall assume that total reflection losses can be kept to 10% . (2) Quantum-yield losses. We have already seen that it is difficult to achieve quantum yields (ϕ_{conv}) close to the optimum values for each scheme. We shall be optimistic and assume that quantum yields can be improved to 90% of the ideal values. (3) Absorption losses. In our calculations we have assumed that all sunlight with $\lambda \leq \lambda_g$ is absorbed and used in driving reaction (1). In real systems the absorption coefficient will vary with wavelength and some sunlight will be absorbed by inactive components. We feel that a realistic goal would be that $\sim 80\%$ of sunlight with $\lambda \leq \lambda_g$ can be absorbed and used. (4) Collection losses. The product gases (at least H_2) must be collected and probably compressed for

storage. There are significant inherent losses in these processes, but we shall be optimistic and assume a collection and storage efficiency of ~90%.

There may be other losses we have not considered; however, when the above estimates are taken into account with $U_{\text{loss}} \sim 0.8$ eV, S2 systems would have efficiencies of ~10%, whereas D4 systems could achieve overall efficiencies of ~16%. If 10% is taken to be a lower limit for a practical device, it is clear that D4 systems have the best chance of realizing such a goal. We have not included 'usage' losses involved in the transportation and use of hydrogen, because these are losses which will be present irrespective of the source.

In summary, claims of high efficiencies for solar water photo-

lysis must be viewed with caution. One must pay especially close attention to the mechanism(s) of the processes and the way in which the efficiencies are calculated³⁹.

ARTICLES

Response of global deep-water circulation to Earth's climatic change 135,000–107,000 years ago

Jean-Claude Duplessy* & Nicholas J. Shackleton†

* Centre des Faibles Radioactivités, Laboratoire mixte CNRS-CEA, 91190 Gif-sur-Yvette, France

† Godwin Laboratory, Free School Lane, University of Cambridge, Cambridge CB2 3RS, UK

The response of deep ocean circulation to major climatic events of the past 135,000 years is inferred using carbon-13 analyses of benthic foraminifera from the major ocean basins. The results demonstrate that the circulation of the world ocean deep water is very sensitive to climate and that it changes drastically during climatic transitions.

COLD bottom and deep waters are found in all ocean basins because, in very limited areas of the world ocean at high latitudes, low-temperature surface water becomes sufficiently dense to sink to a great depth. Since gases are exchanged only at the ocean surface, the deep circulation alone is responsible for the continuous supply of dissolved O_2 , permitting life in the deep sea. The deep water circulation may also play an important part in large-scale climatic fluctuations such that major changes in the deep water circulation are associated with Pleistocene glacial advances and retreats. At least three climatic models have been proposed that also take into account the deep circulation of the oceans¹⁻³. Although none of these models is entirely supported by palaeoclimatic evidence⁴⁻⁶, many deep-sea core studies have suggested that the deep water circulation was drastically different from the present one during the last ice age. For instance,

isotope evidence indicates that the Norwegian Sea was not a source of cold deep water during the last ice age as it is today⁷.

Until now, all studies have dealt with time series of a proxy-indicator in only a few locations. Such studies of deep water circulation used benthic foraminiferal species variation or chemical and isotope composition changes in benthic foraminiferal shells and suggested two major results: (1) that North Atlantic deep water (NADW) was generally forming during the last glaciation; and (2) that its dissolved O_2 content was low because its net production was substantially diminished⁸⁻¹⁰. In this paper, we use a more global approach. Duplessy *et al.*¹¹ demonstrated that the geographical distribution of the ^{13}C isotope composition of Holocene benthic foraminifera reflects that of the total CO_2 dissolved in oceanic deep water. The changes in the global deep water circulation are shown by

Table 1 Core location and depth and O and C isotope composition of benthic foraminifera at three core levels deposited during major climatic events of the period 135,000–107,000 years ago

Core	Lat.	Long	Depth (m)	Isotope stage 6			75% Deglaciation			Isotope substage 5d

comparing maps of the $^{13}\text{C}/^{12}\text{C}$ ratio of benthic foraminifera that lived in deep waters 135,000–107,000 yr ago. The penultimate glacial to interglacial transition and the interglacial to glacial transition which followed are characterized using the benthic foraminiferal isotope analyses that were made as a part of the last interglacial ocean study¹² and those from other measurement programmes. The core locations and isotope values are reported in Table 1.

Hydrological and geochemical basis

Sinking surface waters carry a concentration of dissolved O_2 almost in equilibrium with the atmosphere and a low total CO_2 content resulting mainly from carbon use by phytoplankton for photosynthesis¹³. After their formation, deep waters do not constitute a closed system and they are subject to the addition of CO_2 from two sources, the oxidation of organic matter,

constantly supplied from the surface^{14,15}, and the dissolution of the carbonate of skeletal parts of organisms that live in the overlying waters, but sink towards the bottom after death. Because the organic matter is strongly depleted in ^{13}C (refs 16,17), the CO_2 produced from the oxidation of organic matter has a $\delta^{13}\text{C}$ of -20 to -25 per mil. If this were the only source, the concentration of total CO_2 would be negatively correlated with $\delta^{13}\text{C}$ and with the water O_2 content along the flow path of a deep water mass. In contrast, the CO_2 produced from the dissolution of biogenic carbonate has a $\delta^{13}\text{C}$ fairly close to that of total CO_2 (ref. 18). Consequently, the $\delta^{13}\text{C}$ variations of total CO_2 in the world deep ocean will depend on the relative importance of these two local sources of total CO_2 and are closely correlated with those of the dissolved O_2 content (Fig. 1).

In the Norwegian Sea, surface samples have high O_2 content and high $\delta^{13}\text{C}$ values. The deep waters which are formed by

Fig. 1 $\delta^{13}\text{C}$ in total dissolved CO_2 plotted against dissolved O_2 . Selected data from the deep water masses taken from GEOSECS files and from ref. 45. Pacific values (P) have been measured in deep waters (below 300 m) from stations SCAN X 20, 30, 38, 43 and 56 (ref. 45) and GEOSECS 323 and 347. Indian deep waters (●) (below 3,000 m) data from GEOSECS stations 413, 416, 417, 418, 420, 421, 424, 425, 427, 428, 429, 430, 431, 433, 435, 436, 438, 441, 444, 445, 446, 447, 448, 450, 452 and 453. AABW values (⊕) from GEOSECS stations 33, 39, 42, 46, 49, 53, 55, 64, 68 and 72 below 4,000 m. Eastern Atlantic deep waters (+) from GEOSECS stations 103, 107 and 113 below 3,000 m. Circumpolar current data (○) from GEOSECS stations 76, 78, 82, 89 and 91 below 3,000 m. NADW data (□) from the core of this water mass, as recognized by Kroopnick (refs 20–21), at GEOSECS stations 1, 3, 5, 24, 29, 30, 31, 33, 36, 39, 42, 46 and 49. Each point is the mean of the values measured in the depth range in which the dissolved O_2 is constant; this procedure reduces the scatter in the raw data.

the cooling and sinking of surface waters are the most enriched in ^{13}C in the world ocean. As a result, in the western North Atlantic Ocean, within the core of the southward-flowing NADW¹⁹, the $\delta^{13}\text{C}$ of total CO_2 is high and does not vary significantly, because the North Atlantic is an area of relatively low surface productivity^{20,21}.

In the South Atlantic Ocean, lower $\delta^{13}\text{C}$ values are found as a consequence of the northward flow of Antarctic bottom water (AABW). Dense bottom waters are formed around the Antarctic continent, in the Weddell and the Ross Sea²², without exchanging a noticeable amount of gas with the atmosphere. These bottom waters strongly mix with the overlying Circumpolar water (CPW) and the resulting water masses, which extend northward into each of the deep ocean basins, all have a low dissolved O_2 content and a low $\delta^{13}\text{C}$ value.

The AABW found in the western Atlantic Ocean northward to 30° N can be identified by its low $\delta^{13}\text{C}$ value²¹. Progressive mixing with NADW results in both an O_2 and a $\delta^{13}\text{C}$ increase along this northward-flowing water mass. In the Indian and Pacific Oceans, the major process occurring in the deep water is the *in situ* consumption of organic matter. As a consequence, bottom O_2 concentration and total CO_2 $\delta^{13}\text{C}$ values decrease northwards. A linear relationship is observed between $\delta^{13}\text{C}$ and dissolved O_2 (Fig. 1), indicating that at least in this water mass, $\delta^{13}\text{C}$ is a good proxy-indicator for dissolved O_2 content. The same relationship also applies to AABW, reflecting the common origin of these various water masses.

In the eastern Atlantic Ocean, bottom waters from the south penetrate the Cape Basin but are blocked by the Walvis Ridge. The O_2 content and $\delta^{13}\text{C}$ value of the water below 3,000 m in the Cape Basin are not different from that of AABW and fall on the straight line characterizing waters originating from the south. The more northern basins are filled by bottom water which flows from the western basin of the Atlantic through the Romanche and Vema Fracture Zones in equatorial latitudes.

These waters progressively mix with North Atlantic and Mediterranean waters that are richer in ^{13}C , and their characteristics are intermediate between NADW and AABW.

In summary, the modern distribution of the $\delta^{13}\text{C}$ value of the total CO_2 dissolved in deep and bottom waters of the ocean shows that total CO_2 $\delta^{13}\text{C}$ can be used as a tracer of the deep water circulation under the following conditions: (1) within a deep water mass, the $\delta^{13}\text{C}$ value decreases with increasing oxidation of organic matter, such that the $\delta^{13}\text{C}$ decrease is related both to the surface productivity and to the time elapsed since the deep water was isolated from the atmosphere; (2) when two water masses are compared, the $\delta^{13}\text{C}$ value in each depends not only on their residence time at depth, but also on the ratio between the CO_2 produced from organic matter oxidation and that derived from carbonate dissolution; and (3) mixing between two water masses results in $\delta^{13}\text{C}$ values intermediate between the two original components, regardless of chemical reactions occurring at depth.

^{13}C record of benthic foraminifera

Changing oceanographic conditions that result in changes in both dissolved O_2 content and $\delta^{13}\text{C}$ of total CO_2 , may be reconstructed from the down core ^{13}C record in a deep-sea core. One additional factor which must be taken into account is temporal changes in the $\delta^{13}\text{C}$ content of the global ocean reservoir, which would result from changes in the global biomass^{23,24}.

The $\delta^{13}\text{C}$ value of *Cibicidoides wuellerstorfi* and *C. kullenbergi*, which differs from that of total CO_2 by only $+0.07 \pm 0.04$ per mil¹¹, has been used as a good estimate of the C isotope composition of total CO_2 in the past. This $\delta^{13}\text{C}$ value is 0.90 permil heavier than that of *Uvigerina* at the 95% confidence level. Other species have also been calibrated by comparison with *Uvigerina* or *Cibicidoides*²⁵. Therefore, even if a single benthic foraminiferal species is too rare for analysis throughout the length of a deep-sea core, a complete record of the variations of total CO_2 $\delta^{13}\text{C}$ can be obtained from analysis of several taxa after adjustments have been made to compensate for isotope departure of the taxa from the reference species (*C. wuellerstorfi*).

Figure 2 compares four C and O isotope records of benthic foraminifera in deep-sea cores raised from various ocean basins for the period 135,000–107,000 yr BP. The oxygen isotope records are very similar, in agreement with the hypothesis that the major signal in these records originates from the waxing and waning of large volume of isotopically light water in the Northern Hemisphere ice sheets during the major part of the Pleistocene^{26–29}.

By contrast, the C isotope records exhibit noticeable differences: the amplitude of $\delta^{13}\text{C}$ variations is much larger in the Atlantic cores than in the Indian and Pacific cores⁷. During the transition between glacial stage 6 and interglacial stage 5, $\delta^{13}\text{C}$ values increase in the four cores, but the $\delta^{13}\text{C}$ record lags behind the $\delta^{18}\text{O}$ record in the Atlantic while both records are in phase in the Pacific and Indian Oceans.

Because the $\delta^{13}\text{C}$ value of benthic foraminifera reflects that of the total CO_2 dissolved in the oceanic deep water, the observed differences between the various $\delta^{13}\text{C}$ records indicate that the $\delta^{13}\text{C}$ of total CO_2 in the past ocean has changed not only because of changes in the amount of carbon stored in the exchangeable reservoirs (atmosphere, biosphere and ocean), but also because of changes in the deep water circulation and in the oceanic carbon chemistry^{23,24,30}. Consequently, the major trends of deep water circulation and chemistry in the world ocean during climatic conditions different from those of today can be reconstructed by comparing maps of the $\delta^{13}\text{C}$ of benthic foraminifera that lived at specified times in the past.

Glacial to interglacial contrasts

The $\delta^{13}\text{C}$ distribution of the total CO_2 dissolved in the deep ocean during the last interglaciation (isotope stage 5e, ~122,000 yr ago) has been reconstructed (Fig. 3a) from $\delta^{13}\text{C}$ values of benthic foraminiferal calcite in 41 deep-sea cores raised

Fig. 2 Down core ^{18}O (a) and ^{13}C (b) record from 135 to 107 kyr in four cores, illustrating the temporal change in ^{13}C in distinct regions over the interval covered by this study. The timescale used for the plots is the SPECMAP timescale³³. Core CH 73.139C comes from Rockall Plateau, core M12-392 has been raised from the continental margin off Africa in the tropical eastern Atlantic Ocean. Cores MD 77-202 and V19-30 come respectively from the northern Indian Ocean and from the Panama Basin in the eastern equatorial Pacific, where deep waters are today much older and much more depleted in dissolved O_2 and ^{13}C than those the Atlantic.

from the major ocean basins (see Table 3 of ref. 11 for a list of measured isotope values). This reconstruction shows that deep water sources were active both in the Northern and Southern Hemispheres, both because the highest isotope values are found in the Norwegian Sea and because the $\delta^{13}\text{C}$ values decrease in the Indian and Pacific deep waters according to a pattern similar to present-day conditions. However, the production of AABW was stronger than that of NADW, resulting in an east-west $\delta^{13}\text{C}$ gradient in the Atlantic Ocean higher than the modern one¹¹.

The $\delta^{13}\text{C}$ value of the benthic foraminiferal calcite for each core location during the preceding glacial maximum (isotope stage 6 maximum, ~135,000 yr ago) is reported (Fig. 3b) and the glacial anomaly ($\delta^{13}\text{C}$ difference between the glacial value and the interglacial value) shown in Fig. 3c.

No benthic foraminifera have been found in Norwegian Sea cores V28-60 and K-11 although stage 6 is well represented in the planktonic record. We interpret the absence of benthic organisms as an indication that the Norwegian Sea deep water was sufficiently depleted in O_2 and nutrients to reduce drastically the benthic productivity. This implies no renewal of the deep water and hence that no deep water formed in this basin. The highest $\delta^{13}\text{C}$ values and the smaller anomalies are found in the North Atlantic Ocean (Fig. 3b, c), which indicates the formation of deep water in the northernmost part of this basin, close to the limit of permanent sea-ice³¹. However, in the western Atlantic, the southward extension of this water mass at a depth deeper

than 3,000 m was limited to the high latitudes (core V27-20), because low $\delta^{13}\text{C}$ values are found south of 50°N . By contrast with the interglacial pattern, the western Atlantic was therefore mostly filled by water low in dissolved O_2 and ^{13}C , most probably originating from the Antarctic Ocean, like AABW today.

The lowest $\delta^{13}\text{C}$ values (Fig. 3b) and the highest anomalies ($\delta^{13}\text{C}$ difference between isotope stage 6 and 5e; Fig. 3c) are found in the eastern Atlantic Ocean. This is observed primarily along the coast of Africa. The low $\delta^{13}\text{C}$ values contrast sharply with the interglacial pattern (Fig. 3a) and indicate the production of large amounts of ^{13}C -depleted CO_2 resulting from the oxidation of organic matter produced by the enhanced upwelling activity in this area³². As a consequence, very low $\delta^{13}\text{C}$ values are found off the western coast of Africa (M12-392) and of Portugal (SU81-32). This phenomenon, however, is not strictly coastal and it can be inferred that surface productivity was also enhanced far from the coast, because low $\delta^{13}\text{C}$ values are found in the central North Atlantic Ocean, north of 40°N and below 3,000 m. The $\delta^{13}\text{C}$ values were plotted against depth in the 12 cores north of 20°N for stage 6 and 5e (Fig. 4a, b). The resulting $\delta^{13}\text{C}$ profiles show very distinct features. The interglacial profile exhibits constant $\delta^{13}\text{C}$ values, reflecting an hydrological pattern similar to that of today. On the other hand the glacial profile indicates a strong $\delta^{13}\text{C}$ minimum around 3,200 m and the occurrence of two very different water masses. The first mass was shallower than 2,500 m and consisted of O_2 -rich, high- $\delta^{13}\text{C}$

Fig. 3 Estimates of $\delta^{13}\text{C}$ values of total CO_2 in the oceanic deep water for the last interglaciation (a) and for the penultimate glaciation (b). The glacial anomaly (c) is calculated as the $\delta^{13}\text{C}$ difference between glacial and interglacial values at the same core site. Dashed line indicates the position of the crest of the Mid-Atlantic Ridge.

Fig. 4 Depth profiles of $\delta^{13}\text{C}$ estimates for total CO_2 in deep waters from the Eastern Atlantic Ocean north of 20°N for (a), the penultimate glaciation (isotope stage 6); (b), the last interglaciation (isotope substage 5e); and (c), the beginning of the glaciation (isotope substage 5d).

water which originated in the North Atlantic. The second was a deeper water mass, which was much more depleted in dissolved O_2 and ^{13}C , and probably originated from the western Atlantic deep water. It crossed the Mid-Atlantic ridge through the equatorial fracture zones in the same manner as today. Within this water mass, strong *in situ* consumption of O_2 resulted in a well-developed $\delta^{13}\text{C}$ minimum. Mixing between this water mass and glacial NADW resulted in sharp $\delta^{13}\text{C}$ change with depth in the north-eastern Atlantic Ocean (Fig. 4). This feature is one of the most dramatic aspects of circulation changes between glacial and interglacial periods. Another area exhibiting a strong $\delta^{13}\text{C}$ gradient was the north-western Atlantic Ocean, which was the zone of mixing of the southwards-flowing glacial NADW with the northwards-flowing AABW.

In the Indian and Pacific Oceans, the magnitude of the $\delta^{13}\text{C}$ anomalies is smaller than that of the Atlantic Ocean, suggesting that the stage 6 pattern of deep water circulation was similar to the interglacial one. No indication of formation of deep water and sinking below 1,500 m is provided by the cores raised from the North Pacific Ocean, but our coverage is rather poor and

additional cores are necessary to investigate the sinking of surface water at intermediate depth in the North Pacific. The stronger $\delta^{13}\text{C}$ anomalies are found in the northern and north-eastern area (cores V32-128 and Y72-11-1). The $\delta^{13}\text{C}$ gradient between the equatorial and north-east Pacific is stronger than the modern one, suggesting that the residence time of the Pacific deep water was greater than that of today. A weaker deep-water circulation is also supported by the large anomaly measured in cores raised from the Circumpolar ocean (RC8-79; MD73-025).

Therefore, the pattern of deep water circulation for glacial isotope stage 6 is characterized by weaker fluxes than those of interglacial time and an important reduction in the amount of deep water formed in the Northern Hemisphere, so that most oceanic basins were filled with water originating from the Southern Ocean.

Disappearance of NADW

During the transition from glacial isotope stage 6 to interglacial isotope stage 5e, $\delta^{18}\text{O}$ values of benthic calcite changed from $\sim +5$ per mil to $+3.1$ per mil. To understand the impact of the deglaciation on the deep water circulation, we selected in the cores the level characterized by a $\delta^{18}\text{O}$ value close to $+3.6$ per mil, which would correspond to $\sim 75\%$ of total deglaciation. Using the SPECMAP timescale³³, we estimated the age of this event at $\sim 127,000$ yr BP. In many cores, we have not found benthic foraminifera from that time, despite the detailed sampling made for the CLIMAP reconstruction¹². We believe that this time was unfavourable for benthic productivity, because of either poor oxygenation of the bottom or reduced input of nutrients if the surface productivity was low, as suggested by Ruddiman and McIntyre for the North Atlantic³⁴.

The $\delta^{13}\text{C}$ value of benthic calcite is reported in Fig. 5a. During the deglaciation, the northernmost core (V28-14) exhibits a very low $\delta^{13}\text{C}$ value. This value is much lower than both the glacial and the interglacial values and cannot be explained by any error resulting from bioturbation or foraminiferal abundance offset. Therefore, it indicates a very low renewal of the deep water, as expected in response to the stratification caused by the southward displacement of the limit of sea-ice³⁴. Further south, the $\delta^{13}\text{C}$ contrast between the northern and southern Atlantic Ocean had disappeared. The eastern Atlantic Ocean no longer showed isotopically low $\delta^{13}\text{C}$ values, indicating a sharp drop in the productivity of this basin. A comparison of this with the pattern for isotope stage 6 shows that the most dramatic $\delta^{13}\text{C}$ change during deglaciation occurred in those areas where well-oxygenated water was forming under glacial conditions (cores V28-

Fig. 5 Estimates of $\delta^{13}\text{C}$ values of total CO_2 in the oceanic deep water for (a), 75% of the deglaciation (127 kyr ago) and (b), for isotope substage 5d. The 5d anomaly (c) is calculated as the $\delta^{13}\text{C}$ difference between 5d and interglacial values at the same core site. Dashed line indicates the position of the crest of the Mid-Atlantic Ridge.

14, V27-20, CH73-139C). We interpret this as an indication that deep water formed neither in the northern Atlantic Ocean 127,000 yr ago nor probably during the entire interval of continental ice-melting.

In the Indian and Pacific Oceans, benthic foraminifera that lived during the deglaciation are also scarce. However, the measured $\delta^{13}\text{C}$ values for the benthic calcite are generally isotopically heavier than those of stage 6. As a $\delta^{13}\text{C}$ increase in the Pacific and Indian deep waters cannot occur without deep water circulation, our results demonstrate that some deep water formed in the Southern Ocean during the glacial to interglacial transition, when the North Atlantic deep water source had disappeared.

Enhanced NADW formation

During the phase of rapid ice growth which followed the last interglaciation, the eastern subpolar North Atlantic Ocean maintained warm sea surface temperatures comparable to those of the present-day ocean⁵. This pattern constitutes an optimal configuration for forming deep water in the northern Atlantic Ocean and in the Norwegian Sea. The ocean surface finally cooled late in isotope substage 5d, several thousand years after the mid-point of the ice-growth phase. We chose to reconstruct the $\delta^{13}\text{C}$ pattern of total CO_2 during the maximum of isotope substage 5d (ref. 33), ~107,000 yr ago, because this level can be accurately determined in the cores. At that time, a volume of ice that reached ~50% of the stage 2 full-glacial maximum formed over Northern America and Northern Europe^{35,36}. But we assume that the ocean deep water circulation remained similar to that which prevailed during the inception of the glaciation, because the $\delta^{13}\text{C}$ records do not exhibit major changes between the end of isotope substage 5e and the maximum of 5d (Fig. 2).

The $\delta^{13}\text{C}$ values of benthic calcite during isotope substage 5d are plotted in Fig. 5b and the 5d anomaly ($\delta^{13}\text{C}$ difference between substage 5d and 5e) in Fig. 5c. Isotopically heavy $\delta^{13}\text{C}$ values are found in the Norwegian Sea and in the north-western Atlantic Ocean. A strong positive anomaly in these basins indicate an enhanced flux of the Norwegian Sea overflow water into the North Atlantic Ocean. The high production of NADW may be related to the waxing of continental ice sheets that resulted in an increase of the world ocean salinity. This salinity increase was first experienced in surface waters, which must have received less runoff water during a period of strong evaporation⁵. This process increased the surface density and reduced the density difference between surface and bottom waters, and was therefore favourable to deep-water formation in high northern latitudes.

A western boundary current stronger than today prevailed in the North Atlantic Ocean and maintained a $\delta^{13}\text{C}$ difference between the eastern and western basins much larger than the modern one. Low $\delta^{13}\text{C}$ values and large negative anomalies along the coast of Africa indicate that upwelling was more active than during full interglacial conditions. In the Eastern Atlantic, the surface productivity and the *in situ* consumption of organic matter at depth were higher than today, resulting in the large $\delta^{13}\text{C}$ anomalies shown in Fig. 5c. In contrast with the pattern of stage 6, however, constant $\delta^{13}\text{C}$ values were observed between 2,200 m and 4,000 m, and no strong $\delta^{13}\text{C}$ minimum developed far from the coast (Fig. 4c).

Cores SU81-29 and SU81-32 exhibit a positive $\delta^{13}\text{C}$ anomaly (Fig. 4c). Both are on the path of the Mediterranean Sea overflow water. The Mediterranean Sea is the most important basin of the world ocean where evaporation produces a concentration effect on salt. The hydrological conditions are characterized by high salinity, low productivity and a residence time of the deep water shorter than one century. Consequently, $\delta^{13}\text{C}$ values of total CO_2 are high and similar to those of the Norwegian Sea³⁷. Today, the Mediterranean overflow water serves to increase both the $\delta^{13}\text{C}$ value^{21,37} and the salinity of the North Atlantic Ocean¹⁹. The high $\delta^{13}\text{C}$ values measured in cores SU81-29 and SU81-32 during isotope substage 5d can therefore be interpreted as an indication of a strong outflow of Mediterranean water into the

Atlantic Ocean. Such a pattern, which provides the North Atlantic drift with the high salinity required to form deep waters at high latitudes³⁸, would also serve to increase the production of NADW.

Our coverage is sparse in the Pacific and Indian Oceans and no distinct trends can be recognized, with the exception of low $\delta^{13}\text{C}$ values in the northern Indian Ocean. Because a noticeable decrease in the south-west monsoon was observed at that time³⁹, the upwelling activity was therefore lower than that of the preceding interglacial and the low $\delta^{13}\text{C}$ value of the deep water in the Northern Indian Ocean is best explained by a weaker renewal in this basin.

Wider implications

The reconstruction of the past deep water circulation, which has been a challenge during the past 10 yr, has now become a reality and our approach can be applied to other climatic events. The importance of the deep water circulation changes also suggests that these phenomena can be used to explain the variability of the carbon cycle and the decrease of the atmospheric CO_2 concentration during the last glaciation⁴⁰⁻⁴².

Our results demonstrate that the circulation of the world ocean deep water is very sensitive to climate change. The Southern Hemisphere source of bottom water seems to be one of the most constant features of the circulation of the deep waters. By contrast, the northern source of deep water exhibited a much greater variability, both in location and in intensity. This source was in the open North Atlantic Ocean during the penultimate glacial period and vanished during the following episode of continental ice melting that released a large amount of low salinity water and caused a strong stratification in the North Atlantic Ocean. This source reappeared in the Norwegian Sea during the last interglaciation, and its activity sharply increased during the inception of the last glaciation in response to the increasing salinity of the world ocean. Thus, we conclude that deep water circulation of the world oceans changes drastically during climatic transitions and constitutes an important part of the changing climate system.

Late Eocene-early Oligocene (42-35 Myr) sediments cored at two DSDP sites in the south-west Pacific contain evidence of a pronounced increase in local volcanic activity, particularly in close association with the Eocene-Oligocene boundary. This pulse of volcanism is coeval with that in New Zealand and resulted from the development of an Indo-Australian/Pacific Plate boundary through the region during the late Eocene. The late Eocene/earliest Oligocene was marked by widespread volcanism and tectonism throughout the Pacific and elsewhere, and by one of the most important episodes of Cenozoic climatic cooling.

Two continuous late Eocene through early Oligocene sedimentary sections were recovered during Leg 90 of the Deep Sea Drilling Project (DSDP). These are Sites 592 (36°28.40' S, 165°26.53' E; 1098 m water depth) and 593 (40°30.47' S; 167°40.37' E; 1,068 m water depth), both located in temperate latitudes to the west of New Zealand, on the southern Lord Howe Rise and the Challenger Plateau, respectively (Fig 1). Numerous layers of altered volcanic ash occur throughout the sequences and a 15-m unit of latest Eocene volcanoclastic sediments occurs in Site 593. The Eocene/Oligocene boundary is clearly marked by faunal and floral extinctions and by the universal, marine oxygen isotope shift in both sections. Previously, Site 277, located in the Subantarctic region south of New Zealand, was the only continuous oceanic section spanning the Eocene/Oligocene boundary in the South Pacific. All other sites containing Palaeogene sequences in this region exhibit

hiatuses associated with the Eocene/Oligocene boundary sediments^{1,2}.

Here we attempt to determine the age of the volcanogenic sediments in relation to established stratigraphical markers and discuss the implications of these late Eocene volcanogenic sediments with respect to the palaeotectonic development of both the south-west and the entire Pacific region.

Palaeoenvironmental and biotic events

The record of volcanic activity of late Eocene/earliest Oligocene age is significant because it coincides with a time of major palaeoceanographic change in the world's oceans³⁻⁵. Sequential changes in various biotic elements and in the oxygen isotope composition of calcareous microfossils mark the transition from relatively warm conditions of the middle Eocene to the cooler of the Oligocene. Oxygen isotope evidence indicates that the

cold waters of the oceans (psychrosphere) were generated during the late Eocene/earliest Oligocene when a glacial threshold was crossed in the Antarctic⁶⁻⁸. The record of deep-water cooling is shown first by an oxygen isotope ($\delta^{18}\text{O}$) enrichment at the middle/late Eocene boundary⁶. This deep-water cooling is also reflected by major changes in the deep-sea ostracod faunas between 43 and 40 Myr (ref. 7). Various planktonic faunal and floral elements exhibit a clearly defined trend towards decreasing diversity values during the late Eocene^{9,10}: calcareous nannoplankton exhibit a distinct (70%) reduction in diversity over a 7-Myr period in a stepwise fashion with the most abrupt reduction between the late middle and early late Eocene (41–40 Myr) and a further important reduction across the Eocene/Oligocene boundary¹⁰; planktonic foraminiferal assemblages also changed at several discrete intervals during the late Eocene, with the Eocene/Oligocene boundary marked by an increasing abundance of cool-water forms¹¹. These faunal and floral changes indicate the replacement of warm middle Eocene assemblages with successively cooler assemblages¹⁰⁻¹². The late Eocene cooling trend continued until the Eocene/Oligocene boundary⁵, where further marked cooling is represented by a rapid and distinct $\delta^{18}\text{O}$ enrichment of about 1‰ (refs 6, 13–15). This shift, isochronous according to planktonic foraminiferal biostratigraphy¹⁶, gave rise to maximum earliest Oligocene $\delta^{18}\text{O}$ values, which were followed by lower (lighter) values later in the Oligocene¹⁶. Associated with this event was a significant drop of up to 2,000 m of the calcium carbonate compensation depth and related oceanwide lithofacies changes¹⁷. Faunal and floral assemblages underwent distinct, but not drastic, catastrophic changes at the Eocene/Oligocene boundary^{12,18}.

The Eocene/Oligocene boundary is biostratigraphically linked with the last abundant disappearances of the *Globorotalia cerroazulensis-coccolensis* group, *Hantkenina* and *Globigerinatheka* and the rosette-shaped discoasters including *Discoaster barbadensis* and *D. saipanensis*¹⁹. These occur within a relatively brief interval between 36.1 and 37.4 Myr (base anomaly 13-top anomaly 15). An age of between 36.5 and 37 Myr has been suggested for the Eocene/Oligocene boundary¹⁹, which is close to that determined elsewhere (37.1–37.2 Myr)^{20,21}.

Deep-sea sequences

Site 592 provides a particularly fine, highly expanded 90-m section of late Eocene to early Oligocene sediment (Fig. 2). A distinct lithological change from calcareous ooze to chalk occurs below the extinction level of the foraminifer *Globigerinatheka index*. This extinction is often used to mark the Eocene/Oligocene boundary in south-temperate latitudes and is the marker used here. The underlying late Eocene sequence is largely represented by nannofossil chalk containing siliceous microfossils such as Radiolaria and sponge spicules, whereas the Oligocene is represented by surprisingly soft nannofossil ooze lacking biosiliceous material.

The extinction of *G. index*, marking the Eocene/Oligocene boundary, is in Core 36-3 between 90 and 64 cm. According to the calcareous nannoplankton markers, the Eocene/Oligocene boundary would be placed at the extinctions of *D. saipanensis* and *D. barbadensis*, which is in Core 37-2, between 5–6 and 33–34 cm. The time period between these two sets of extinctions is ~0.4 Myr (ref. 22). A similar sequence of extinctions of the two groups was recorded at DSDP Site 277 drilled south of New Zealand²³. Relevant species ranges are shown in Fig. 2, with assigned calcareous nannoplankton and planktonic foraminiferal zones.

The $\delta^{18}\text{O}$ record in Site 592 (Fig. 2) exhibits relatively constant late Eocene values followed by a rapid decrease (~0.4‰) and then a distinct increase (~1.0‰) beginning at the base of Zone NP21, which is considered to represent the Eocene/Oligocene boundary based on calcareous nannoplankton biostratigraphy. This oxygen isotope shift continued until the latest part of Zone NP21. The Eocene/Oligocene boundary based on planktonic foraminifera (last appearance of *G. index*) occurs near the

Fig. 1 Location of DSDP Sites 592, 593 and 277 in the south-west Pacific. Present-day positions shown of three lithospheric plates and their boundaries. Also shown are present-day positions of the Polar Front that separates Antarctic from Subantarctic surface waters and the Subtropical convergence that separates Subantarctic from cool-subtropical (temperate) water masses.

beginning of this oxygen isotope shift. The values then slightly decrease (~0.2‰) from the peak associated with the NP21/NP22 boundary and steadily decrease with little variation during the remaining early Oligocene. There is remarkable parallelism of planktonic and benthic oxygen isotope variations. Detailed interpretations of the oxygen isotope records for Sites 592 and 593 are provided elsewhere²⁴.

Site 592 contains many (4–29 laminae per 9 m core length) thin, altered, pale green volcanic ash layers (Fig. 2) in the late Eocene to early Oligocene (~42–35 Myr). Such layers are absent in the Neogene section of Site 592 except for rare occurrences in the middle Miocene and common occurrences (2–12 laminae per 9 m core length) in the Quaternary^{25,26}.

A spectacular sequence over the Eocene/Oligocene boundary is recorded at Site 593 (Fig. 3). Close to the boundary is a remarkable 15-m sequence of greyish black to greyish green, well-lithified volcanoclastic breccia, sandstone and mudstone, including possible ash tuff, between 546 and 561 m. These sediments are basaltic in composition and are interpreted as proximal turbidites, debris flows and pyroclastic flows²⁷. They represent the 'only non-carbonate lithological units drilled at either of the two sites, and are rare for open-ocean pelagic sequences. The unit consists of at least 40 subunits that exhibit finer-grained sediments upwards, and are, typically 20–50 cm thick. Several of the subunits exhibit a partial Bouma sequence of sedimentary structures (dominantly divisions A and B). The internal structure of the individual subunits, especially the predominance of Bouma A and B divisions compared with B and E divisions, suggest proximal rather than distal deposits, although some of the coarser beds may be submarine pyroclastic flows. The source is almost certainly the nearby buried Lalitha Volcanic Pinnacle^{25,27}, ~2 km from Site 593, and conspicuous on seismic records. The volcanoclastic unit can be traced for several tens of miles to the north on the seismic profile. This unit is confined to a relatively short time interval because most of the remaining seismic section is marked by relatively acoustic transparency²⁵. The volcanoclastic rocks are underlain by nanno chalk at the base of the hole that contains many thin laminae of altered volcanic glass indicating episodes of explosive volcanism. As in Site 592, the Eocene/Oligocene boundary, as defined by the extinction of *G. index*, is again younger than that marked by the extinction of *D. saipanensis* (Fig. 3). The volcanoclastic unit was emplaced between these two dates and is thus of latest Eocene age. The Eocene/Oligocene boundary occurs at ~3.38 m above the top of the volcanic unit at ~57–90 cm (Fig. 3). The extinction of *D. saipanensis* occurs at the base of the volcanic

Fig. 2 Late Eocene early Oligocene biostratigraphy and oxygen isotopic stratigraphy of DSDP Site 592 showing quantitative distribution of altered volcanic ash laminae in the sequence. Recovered sediment sections shown by black in left column. Oxygen isotopic curves are for the benthic foraminifer *Oridorsalis umbonatus* and the planktonic *Globigerina angiporoides*. Also shown are calcareous nannoplankton zones designated as NP and NN Zones^{22,25} and planktonic foraminiferal zones^{25,35}. Eocene/Oligocene boundary is placed at the last appearance of *Globigerinatheka index*.

Fig. 3 Late Eocene through early Miocene biostratigraphy and oxygen isotopic stratigraphy of DSDP Site 593 and stratigraphical position of 15-m volcanoclastic unit of latest Eocene age. Oxygen isotopic curves are for the benthic foraminifer *Oridorsalis umbonatus* and the planktonic foraminifera *Globigerina angiporoides* and *G. cf. antiporoides*. Also shown are calcareous nannoplankton zones designated as NP and NN Zones^{22,25} and planktonic foraminiferal zones^{25,35}. Eocene/Oligocene boundary is placed at the last appearance of *Globigerinatheka index*.

material (Fig. 3). A radiometric determination of the volcanic material was not possible because of extreme submarine alteration (I. McDougall, personal communication); however, a latest Eocene age for the volcanics is consistent with the reversed geomagnetic polarity of the volcanoclastic sequences that suggests deposition during Magnetic Subchron C13R at ~37 Myr (refs 20, 21).

The $\delta^{18}\text{O}$ record (Fig. 3) exhibits a clear shift of 1.0‰ beginning in the late Eocene, just below the volcanoclastic unit, and reaching a maximum in early Oligocene Zones NP21/22. A gradual 0.5‰ decrease in early Oligocene $\delta^{18}\text{O}$ values was followed by a stepped increase of 0.5‰ in the late/early Oligocene; the $\delta^{18}\text{O}$ values gradually decrease 0.6‰ during the middle Oligocene²⁴. The volcanogenic unit was therefore emplaced during the well-known oxygen isotopic shift that marks the terminal Eocene.

Increased New Zealand volcanism

The pale green volcanic laminae, so abundant in the late Eocene/early Oligocene in Site 592 and in the late Eocene of Site 593, represent deposits resulting from highly active explosive volcanicity in the south-east Tasman Sea region. The volcanoclastic unit of latest Eocene age in Site 593 was derived from basaltic eruptions on the sea floor, with most of the massive

material mass-emplaced by pyroclastic or debris flows. The well-bedded and normally graded units were probably redeposited and sorted downslope by turbidity currents. Following deposition, the predominantly glassy sediments were extensively metasomatized and hydrated by the action of low-temperature seawater or by weathering phenomena, as shown by the abundance of smectite and phillipsite^{26,27}.

The Lalitha Pinnacle, the probable source of the latest Eocene volcanoclastic deposits, is one of several small pinnacles observed on seismic profiles on the Challenger Plateau²⁸ and on the southern Lord Howe Rise^{27,29}. These pinnacles were previously considered to have been formed between the middle Eocene and middle Miocene²⁹. Morphological similarity and the position of the other pinnacles in the seismic profiles suggests that the pinnacles are also of late Eocene age. The widespread nature of these volcanic centres and the abundance of altered volcanic ash layers in the late Eocene/early Oligocene sequences in comparison with the absence or rarity in the remainder of the Cenozoic clearly indicates intensified volcanism at this time in the New Zealand region. This conclusion is supported by the evidence for widespread volcanism of similar age in uplifted sections on New Zealand³⁰. These include the late Eocene basaltic Waiareka Volcanic Formation of north-east Otago³¹; the late Eocene/earliest Oligocene section of the Kekerione

Group of the Chatham Islands³²; and, in part, the Matakaoa Volcanics of East Cape³³. The basaltic Tangihua Volcanics of Northland are, in part, of late Eocene age, although their stratigraphical range is much older³⁰. The Tangihua and Matakaoa Volcanics have been interpreted as ancient seamounts³⁴. In north-east Otago, the Deborah Volcanic Formation (alkaline basalts, tuffs and agglomerates) was deposited within the *G. brevis* Zone and after the extinction of *G. index*^{35,36}, and thus is of earliest Oligocene age. North Canterbury and south Marlborough contain a fairly widespread submarine volcanic episode approximately coeval with the Deborah Volcanics, including the Cookson Volcanics consisting of widespread tuffs and less widespread basaltic pillow lavas^{30,37}. Much of this late Eocene/earliest Oligocene volcanism is localized and has been interpreted to be submarine in origin^{30,34}. In general, the Palaeogene of New Zealand, with the notable exception of the middle/late Eocene, represents a time of relative volcanic quiescence³⁰. The late Eocene also recorded the establishment of rapid subsidence and infilling of sedimentary basins in western South Island that resulted from locally increased tectonic activity^{38,39}.

Tectonic significance

The increase in late Eocene/early Oligocene volcanism and tectonism coincided with and was related to a change at 38 Myr in the pole of rotation that caused the development of an active tectonic zone through New Zealand^{38,40,41}. This active tectonic zone developed in association with the link-up of the South Pacific Rise with the south-east Indian spreading axis between Australia and Antarctica^{41,42}. A northward propagating zone of extension developed from the spreading ridges south of New Zealand along the western part of New Zealand as a linear zone of subsiding basins³⁹. Right-lateral movement may have developed along this zone as it linked up with basins to the north of New Zealand⁴¹, thus forming an extensional transform boundary across the New Zealand plateau⁴⁰. This effectively represented the development of an Indo-Australian/Pacific plate boundary in the latest Eocene^{38,43,44}. Increased explosive volcanism recorded in late Eocene sediments over wide areas of southern Australia has been linked to plate tectonic developments between Australia and Antarctica⁴⁵. Also an active phase of marginal basin development in the south-west Pacific marginal basins north of New Zealand⁴⁶ and eruption of basalts in New Caledonia during the late Eocene/early Oligocene⁴⁷ may have been associated with the development of this plate boundary. As yet, it is not clear as to the causal relations of the known New Zealand volcanism to the plate boundary, as this is located on either side of the main locus of deformation related to plate boundary development, rather than the eventual line of the boundary.

Circum-Pacific orogeny and volcanism

There is evidence that the pulse of volcanic activity during the late Eocene/earliest Oligocene in the south-west Pacific may have occurred throughout the circum-Pacific region. Pulses of explosive volcanicity have previously been recognized during the Neogene in the Circum-Pacific⁴⁸ and the Cenozoic in the North Atlantic⁴⁹. In Japan, there was a pulse of volcanicity during the late Eocene/earliest Oligocene (41–36 Myr)⁵⁰ related to termination of the Shimanto Orogeny^{51–53} and to initiation of the Mizuho tectonic phase in north-east Japan⁵⁴. In the Philippine Basin, there was a late Eocene pulse of island-arc related volcanism⁵³; and the Peruvian Andes show an important increase in volcanism during the late Eocene (~40 Myr) followed by a period of quiescence through most of the Oligocene⁵⁵.

Although we believe that the late Eocene volcanism in the New Zealand region was related to the development of a plate boundary through the area at that time, the Pacific-wide increase in volcanism was probably associated with a broader series of late Eocene plate-tectonic changes. The greatest late Phanerozoic change in Pacific Plate motion occurred during the late Eocene at ~42 Myr. This is most conspicuously reflected by the

bend in the Hawaiian–Emperor volcanic chain, located near the Yuryaku and Kanmu seamounts. Radiometric ages provide an age of these seamounts, and thus the bend, as between 41 and 43 Myr with the best weighted average of 42.3 ± 1.6 Myr (ref. 56). At this time, the volume of erupted volcanic material increased in the chain⁵⁷. The change in Pacific Plate motion is also recorded by a pronounced change in direction of the Mendocino Fracture Zone reflecting reorientation in spreading between the Pacific and Farallon Plates⁵⁸. SEASAT altimeter data exhibit a change in direction of the Eitanin and Udintsev Fracture Zones, reflecting plate motion change between 35 and 45 Myr, close to the age of the Hawaiian–Emperor bend⁵⁹.

Following this change in rotation of the Pacific Plate, there was an active phase in marginal basin development in the south-west Pacific, overthrusting of New Caledonia ultramafics and formation of new island-arc systems^{46,60}; increased late Eocene orogeny in Japan⁵⁴; and the initiation of the Philippine, Bonin, Mariana, Yap, Palau and Tonga trench-arc systems along former north-south trending fracture zones during the late Eocene⁶¹. In south-east Asia, there was a period of plate reorganization during the latest Eocene and early Oligocene⁶², and the Indian Ocean showed a coeval increase in spreading rate on the south-east Indian Ridge⁶³ as well as major change in spreading directions on both the south-west Indian Ocean and the Central Indian Ridges⁶⁴.

Turning points in the tectonic development of the Earth's major orogenies occur contemporaneously with first-order readjustments in plate tectonic motions because of the geotectonic-mechanical connections between the lithospheric plates^{65,66}. Each major change in the interlocking global stress system of plates may have global effects in mobile zones and may explain the near simultaneous increases in tectonism and volcanic activity⁶⁵. The northward motion of the Indian plate has slowed down from about 10 to 5 cm yr⁻¹ since the collision between India and Eurasia commenced at about 40 Myr (ref. 67). Also, the late Eocene (42–38 Myr) was a time of intense orogeny as represented by the Illyrian (Pyrenean) orogenic phase in the north Atlantic and Mediterranean regions^{65,66}. The Illyrian phase may have resulted from an abrupt change in the relative movement between the African and Eurasian plates. Such orogenic episodes have alternated with periods of relative tectonic quiescence^{65,69}.

Palaeoenvironmental significance

The late Eocene to earliest Oligocene was one of the most important intervals of global climatic cooling during the Cenozoic, especially at high latitudes^{3,4,13}. Increased biotic extinctions resulted from these environmental changes, although, unlike those associated with the terminal Mesozoic event, they were not of massive (catastrophic) proportions⁵ and the planktonic microfossil extinctions seem to have been concentrated in the extratropical areas where the cooling occurred. Several mechanisms, both terrestrial and extraterrestrial, have been proposed to explain the biotic and climatic changes that occurred during the terminal Eocene event^{3,70–75}. The problem of the causes of the terminal Eocene event is not without parallel with that of the terminal Mesozoic event, since catastrophic, extraterrestrial mechanisms have been invoked for each^{72,73,76}. Furthermore, the terminal Mesozoic event has recently been linked to a major increase in global volcanic activity⁷⁷. We believe that global climatic cooling during the terminal Eocene event, associated with increased Antarctic glacial development was created by fundamental changes in ocean circulation resulting from plate tectonics^{3,24}. Increased late Eocene explosive volcanism, related to the changes in plate tectonics, may also have contributed to this climatic cooling⁷⁸.

We thank Captain J. Clark and the crew of the *Glomar Challenger* for their most professional assistance during DSDP Leg 90. M. McHugh drafted the figures and N. Meader typed the manuscript. This contribution was partly supported by NSF grant DPP84-16687 to J.P.K.

The cloned complementary DNA sequence encoding the human gonadotropin-releasing hormone (GnRH) precursor protein was used to construct an expression vector for the bacterial synthesis of the 56-amino acid GnRH-associated peptide (GAP). GAP was found to be a potent inhibitor of prolactin secretion and to stimulate the release of gonadotropins in rat pituitary cell cultures. Active immunization with peptides corresponding to GAP sequences led to greatly increased prolactin secretion in rabbits.

MAMMALIAN reproduction is centrally controlled through the synthesis and release of the decapeptide gonadotropin-releasing hormone (GnRH) by hypothalamic neurosecretory cells. The pulsatile secretion of this peptide into the vascular system connecting hypothalamus and pituitary triggers the episodic release of luteinizing hormone (LH) and follicle-stimulating hormone (FSH) from gonadotrophic cells in the anterior pituitary^{1,2}. Additional, but less well understood, reproductive functions of GnRH are suggested by its synthesis in tissues such as gonads, placenta, mammary glands and extrahypothalamic regions of the central nervous system³⁻⁷.

That such synthesis in diverse tissues is the product of the same gene in human and rat has been established recently in our laboratory using recombinant DNA technology. Thus, complementary DNA clones containing coding sequences for a

GnRH precursor protein of relative molecular mass 10,000 (M_r) have been isolated from libraries derived from human placental⁸ and from human and rat hypothalamic messenger RNA⁹, and genomic analyses in both species revealed the presence of a single gene encoding this protein⁹.

The structure of the biosynthetic GnRH precursor as predicted from cloned nucleotide sequences⁸ comprises the decapeptide preceded by a signal sequence of 23 amino acids and followed by a Gly-Lys-Arg sequence necessary for enzymatic processing and carboxy-terminal amidation of GnRH. A sequence of 56 amino-acid residues occupies the carboxy-terminal region of the precursor and constitutes the GnRH associated peptide, GAP.

The central role of this precursor in reproduction and its resemblance to other peptide precursors from which multiple products having separate functions can be generated (see ref.

Fig. 1 Structure and encoded amino-acid sequence of human placental cDNA for prepro-GnRH⁸. **a**, Partial restriction endonuclease map. The coding region is located between the initiation codon for protein synthesis ATG and the termination codon TAA. Schematic representation of the encoded protein identifies the three domains of signal peptide, GnRH and GAP with the respective sizes in amino-acid (aa) residues. **b**, Amino-acid sequences of GnRH and GAP with an enzymatic processing site separating the two moieties. Numbers refer to the respective positions within GnRH(1-10) or GAP(1-56).

10 for review) had suggested the possibility that GAP is secreted together with GnRH to modulate pituitary function. Further evidence for this possibility was provided by our finding that antigenic determinants from GAP could be visualized in secretory vesicles in hypothalamic neurones, using immunocytochemistry¹¹.

As a step towards evaluating this possibility, we synthesized the 56-amino-acid peptide using recombinant DNA technology. A bacterial expression vector was constructed containing the coding sequences for GAP. This peptide was purified from bacterial extracts and tested for its activity on the secretion of anterior pituitary hormones using rat primary cell cultures. We report here that GAP inhibits prolactin release at subnanomolar concentrations and may represent the postulated peptide prolactin release-inhibiting factor (PIF)^{12,13}. GAP also displays gonadotropin-releasing activity with a concentration-response

curve similar to GnRH. Generation of gonadotropin-releasing and prolactin release-inhibiting activities from the same precursor protein may account for the known inverse relationship of LH/FSH and prolactin levels during certain physiological states of reproduction and lactation¹³⁻¹⁵.

Expression and purification of GAP

The structure of cloned human placental cDNA encoding the GnRH precursor is shown in Fig. 1, together with the deduced protein sequence. The coding sequences of this cDNA were used in the construction of a bacterial expression vector for the production of the 56-amino-acid GAP. As human GAP contains no methionine residues, we expressed this peptide as the carboxy-terminal part of a fusion with the *Escherichia coli* protein trpΔLE1413 (ref. 16) after introducing a methionine codon between the bacterial and human coding sequences. The presence of a methionine residue in this position allowed for the release of GAP by cyanogen bromide (CNBr) cleavage of the fusion protein produced by *E. coli*¹⁷.

As illustrated in Fig. 2, a DNA restriction fragment carrying the coding sequences for amino-acid residues 8-56 of GAP was isolated from plasmid DNA carrying the cloned cDNA and ligated to synthetic DNA encoding the first six amino acids of GAP preceded by a methionine codon and an *EcoRI* cohesive end. This ligation step also reconstituted GAP codon 7. An in-phase termination codon was created by cleaving the semi-synthetic DNA fragment with endonuclease *AhaIII* and inserting the resulting 177-base pair (bp) DNA into *EcoRI*/*HincII*-cleaved M13 mp18 replication form DNA¹⁸. The newly constructed GAP gene was isolated following primed DNA synthesis from recombinant M13 DNA as an *EcoRI*/*HindIII* DNA fragment and joined in-frame to the coding sequences of the *E. coli* trpΔLE1413 gene.

E. coli cells transformed with the resulting plasmid ptpLE-GAP were grown under conditions of tryptophan depletion and cell extracts were analysed for the presence of the fusion protein by SDS-polyacrylamide gel electrophoresis and immunoblots¹⁹ made using a GAP-specific antibody¹¹. The bacterial cells produced high levels of a GAP-immunoreactive protein of $M_r \sim 27,600$, a M_r expected from its genetically engineered size of 247 amino acids comprising 190 residues of the trpΔLE1423 protein plus the 57 amino acids of the Met-GAP peptide (Fig. 3B). *E. coli* cells containing the plasmid ptpLE-GAP were grown by high-density fermentation which yielded the fusion protein in the form of insoluble refractile bodies facilitating purification²⁰.

Protein purification was achieved by a combination of gel permeation and reverse-phase HPLC. The fusion protein was purified on a semi-preparative scale by reverse-phase HPLC with ~60% recovery from the refractile body preparation. CNBr treatment of this protein resulted in the release of GAP and additional fragments derived from the trpLE protein (Fig. 3A).

Table 1 Effect of GAP on the secretion of hormones from rat anterior pituitary cell cultures compared with basal levels and effects of known hypophysiotropic hormones

	LH	FSH	Prolactin	ACTH	GH
Basal	7.2 ± 0.59	2.56 ± 0.67	1,819 ± 193	66.2 ± 9.9	722 ± 112
GnRH	68.8 ± 6.52	11.2 ± 0.86	1,781 ± 351	74.6 ± 14.8	727 ± 67
TRH	ND	ND	3,032 ± 395	ND	ND
CRF	ND	ND	ND	287.1 ± 32.0	ND
GRF	ND	ND	ND	ND	3,080 ± 690
GAP	47.3 ± 5.16	7.3 ± 0.61	922 ± 106	73.2 ± 11.4	664 ± 117

Anterior pituitaries from female Sprague-Dawley rats (200-250 g) were dispersed by enzymatic treatment and cells kept in 24-well culture plates (5×10^5 cells per well) in medium 199 supplemented with 10% fetal bovine serum for 3-4 days when medium was changed as described previously^{31,32}. Incubations with the peptides GnRH, TRH, GRF (all from Peninsula Labs) and GAP were performed on the 4th or 5th day of culture in serum-free medium. 10^{-8} M concentrations of the peptides, except 10^{-7} M of TRH, were incubated with the cells for 4 h when media were removed and assayed for rat prolactin (PRL), LH, FSH and GH by double-antibody radioimmunoassay. Values are expressed in terms of recombinant PRL-RP-3, rLH-RP-2, rFSH-RP-2 and rGH-RP-2 reference proteins. ACTH was determined by radioimmunoassay as described previously³³ and is expressed in terms of pACTH. In a given cell culture, experimental points were determined from four parallel culture wells of which media were assayed by radioimmunoassay in duplicate. Values given for LH, FSH and prolactin are means ± s.d. of five independent cell cultures and those for ACTH and GH were from two cell cultures. All values are in ng per 5×10^5 cells $\times$ 1 ml medium $\times$ 4 h. ND, not done.

Fig. 2 Construction of plasmid *ptrpLE-GAP* DNA for the expression of GAP in *E. coli*. Amino-acid sequence numbers refer to positions in the GAP sequence.

Methods. The plasmid *pGnRH-1*, which contains the entire coding sequence for prepro-GnRH, was derived by subcloning a 568-bp *EcoRI*/*PstI* fragment from λ LHRH-1 (Fig. 1) into plasmid pUC11 (ref. 56). *pGnRH-1* DNA (15 μ g) was cleaved with *HinfI* and a 1,778-bp *HinfI* fragment was purified by polyacrylamide gel electrophoresis and subsequent electroelution. The two deoxyoligonucleotides, 5'-dAATTCATGGATGCCGAAATCTGATTG (fragment 1) and 5'-dAATCAATCAGATTTTCGGCATCCTAG (fragment 2), were chemically synthesized⁵⁷ and purified by gel electrophoresis. Fragment 2 (380 pmol) was phosphorylated at 37 °C for 30 min in a 20- μ l reaction containing 50 mM Tris-HCl (pH 8.0), 10 mM MgCl₂, 10 mM dithiothreitol (DTT), 1 mM ATP and 2 U T₄ polynucleotide kinase. The kinase was inactivated by heating the reaction to 100 °C for 3 min. Approximately 3 pmol (~3 μ g) of the 1,778-bp *HinfI* fragment was ligated to synthetic DNA in a 40- μ l reaction containing 50 mM Tris-HCl (pH 8.0), 10 mM MgCl₂, 10 mM DTT, 1 mM ATP, 150 pmol fragment 1, 150 pmol phosphorylated fragment 2 and 10 U T₄ DNA ligase. The ligation reaction was allowed to proceed for 2 h at ambient temperature before the ligase was heat-inactivated at 70 °C for 15 min. The DNA was then cleaved with *AhaIII* and electrophoresed on a 6% polyacrylamide gel. The correct 177-bp *EcoRI*/*AhaIII* DNA fragment was recovered by electroelution and ~7 ng was mixed with 10 ng *EcoRI*/*HincII*-cleaved M13 mp18 RF-DNA¹⁸ in a 20- μ l reaction containing 50 mM Tris-HCl pH 8.0, 10 mM MgCl₂, 0.1 mM EDTA, 1 mM ATP and 2 U T₄ DNA ligase. Transformation of JM101 cells using the ligated DNA produced many recombinant (white) plaques of which three were picked, grown and subjected to sequence analysis^{58,59} to confirm the correctness of the construction. Single-stranded mp18-GAP DNA was made double-stranded *in vitro* by elongating the 17-mer *lac* primer⁵⁹ in the presence of 1 mM deoxynucleotide triphosphates and *E. coli* DNA polymerase (Klenow). A 187-bp *EcoRI*/*HindIII* fragment was released from the resulting double-stranded DNA by *EcoRI*/*HindIII* cleavage and purified by polyacrylamide gel electrophoresis. The expression plasmid (*ptrpLE*, a derivative of pNCV-1 (ref. 20) containing a polylinker region and an ampicillin resistance gene) was cleaved with *EcoRI* and *HindIII* and ligated to the 187-bp *EcoRI*/*HindIII* fragment containing the GAP coding sequence. *E. coli* K-12 strain 294 cells were transformed with the ligation reaction and ampicillin resistant (*Amp*^R) colonies were screened by hybridization⁶⁰ for the presence of GAP sequences. Positively hybridizing clones were screened for their ability to synthesize a *trpLE-GAP* fusion protein (see Fig. 3). The sequence of one recombinant, *ptrpLE-GAP-26*, which produced the highest levels of fusion protein, was checked by supercoil sequencing⁶¹.

CNBr and formic acid were removed using reverse-phase HPLC and the cleavage products of the fusion protein were eluted by a step gradient. Given the significant size differences of these cleavage products, gel permeation chromatography was used to separate GAP from side products. The fraction containing the immunoreactive material was further purified by reverse-phase HPLC to homogeneity (Fig. 3C). Amino-terminal sequence analysis through 10 cycles confirmed the expected structure of the peptide (data not shown). Amino-acid analysis agreed with the theoretical composition of the molecule (see Fig. 3 legend). Polyacrylamide gel electrophoresis of purified GAP showed the presence of a single band immunoreactive after transfer to nitrocellulose (not shown).

Effect of GAP on hormone secretion

Primary cell cultures of the anterior pituitary have been extensively used to study the action of hypothalamic hypophysiotropic hormones. Recently, cultures of rat anterior pituitaries have aided the isolation and identification of corticotropin-releasing factor (CRF) and growth hormone-releasing factor

(GRF) of human and ovine origin²¹⁻²³. Using such cultures, we evaluated the effect of GAP on the secretion of LH, FSH, prolactin, corticotropin (ACTH) and growth hormone (GH). GAP was used at a concentration of 10⁻⁸ M, which for most hypophysiotropic hormones elicits maximal response from anterior pituitary cell or organ cultures. The effect of GnRH, thyrotropin-releasing hormone (TRH), CRF and GRF which stimulate gonadotropin, prolactin, ACTH and GH secretion, respectively, were also evaluated in parallel incubations. GAP did not affect the secretion of ACTH and GH but markedly influenced the secretion of LH, FSH and prolactin (Table 1). Although GAP stimulated the release of both gonadotropins, the peptide inhibited the basal secretion of prolactin by ~50%, comparable to inhibition levels reported for dopamine, a known prolactin-inhibiting factor^{24,25}.

Gonadotropin-releasing effect of GAP

Similar to GnRH¹, increasing concentrations of GAP caused an increase in both LH and FSH secretion from rat anterior pituitary cells, although maximal release was higher for GnRH

Fig. 3 Bacterial expression and purification of GAP. **A**, Schematic structure of the trpLE-GAP fusion protein indicating the location of methionines (M) and the GAP region. **B**, Analysis of total cellular proteins in *E. coli* K-12 strain 294 transformed with plasmid ptrpLE-GAP (**d**) and the purified trpLE-GAP fusion protein (**c**). Lanes **b** and **a** represent immunoblots¹⁹ of **d** and **c**, respectively. Relative molecular mass markers electrophoresed in parallel are shown in lane **e**. **C**, Analytical reverse-phase HPLC of purified GAP showing 210-nm absorbance profile. The peptide was chromatographed in conditions described below.

Methods. *E. coli* K-12 strain 294 cells containing the plasmid ptrpLE-GAP were grown in M9 medium containing 50 $\mu\text{g ml}^{-1}$ ampicillin. An aliquot of the cells was lysed in 2% SDS, 1% β -mercaptoethanol and precipitated with 10 vol of cold acetone. Samples were electrophoresed on 12.5% discontinuous SDS gels²² and proteins were either stained with Coomassie brilliant blue or transferred to nitrocellulose¹⁹. The latter was incubated with a GAP-specific antibody¹¹ and the cross-reacting protein visualized using horseradish peroxidase coupled to a second antibody followed by reaction with 4-chloro-1-naphthol¹⁹. For a 10-l high density fermentation culture, the plasmid ptrpLE-GAP was transferred to the *E. coli* K-12 strain W3110. Refractile bodies prepared as described previously¹⁷ were solubilized in 6 M guanidine hydrochloride containing 1% β -mercaptoethanol by vigorous stirring for 24 h at room temperature. The extract was then dialysed into 4 M urea and applied onto a Vydac C₄ 300 Å, 15–20 μm , 5 $\times$ 35 cm column and chromatographed using a gradient of 25–60% acetonitrile per 0.1% trifluoroacetic acid (TFA). Fractions containing GAP-27-40-immunoreactive material as tested by dot-blots⁶³ were pooled and lyophilized to yield 3.4 g fusion protein. 1.6 g of this material was subjected to CNBr cleavage and the reaction mixture, following dilution with 0.1% TFA, was chromatographed on a Vydac C₁₈, 300 Å, 15–20 μm , 2.5 $\times$ 35-cm column using a gradient of 30–50% acetonitrile containing 0.1% TFA. The fractions containing 6.200-M_r immunoreactive material were pooled and lyophilized to yield 285 mg crude GAP. This material was dissolved in 2 M acetic acid and subjected to gel filtration on a Sephadex G-50, 2.5 $\times$ 85 cm column eluting with 2 M acetic acid. 10 mg of the immunoreactive fraction (102 mg) was further purified by reverse-phase HPLC on a Vydac C₄, 300 Å, 5 μm , 1 $\times$ 25 cm column using a gradient of 33–45% acetonitrile/0.1% TFA to yield 1.3 mg GAP. Approximated amino-acid analysis, with theoretical values in parentheses: Asp, 4.65 (4); Thr, 3.98 (4); Ser, 2.99 (3); Glu, 13.67 (14); Gly, 3.20 (3); Ala, 3.31 (3); Val, 2.28 (2); Ile, 3.70 (4); Leu, 6.58 (6); Phe, 2.00 (2); His, 1.28 (1); Lys, 3.72 (4); Arg, 3.30 (3). Analytical HPLC conditions of **C**: Sample, 20 μg GAP in 25 μl 0.1% acetic acid; column, Vydac C₄, 300 Å, 5 μm , 0.5 $\times$ 25 cm; mobile phase, acetonitrile per 0.1% TFA; gradient: 36% to 44% in 30 min; detection: 210 nm at 0.25 absorbance units full scale (AUFS).

than GAP. Half-maximal stimulation of LH release by GAP occurred at higher concentrations than by GnRH (2×10^{-9} M for GAP compared with 8×10^{-10} M for GnRH). In contrast, GAP stimulated FSH secretion at approximately the same concentrations as GnRH with half-maximal effective dose (ED_{50}) values of the order of 5×10^{-10} M (Fig. 4b). There was no significant additive effect when cells were incubated with both GnRH and GAP.

Our finding that an additional peptide derived from the GnRH prohormone stimulates gonadotropin secretion has new implications for the potential selective regulation of LH and FSH release. Indeed, GAP alone shows a definite preference for stimulating FSH secretion as reflected in the ED_{50} values of LH (2×10^{-9} M) and FSH (5×10^{-10} M) release by the peptide (Fig. 4). The cause and physiological significance of this differential stimulation are unknown. As the simultaneous presence of GnRH and GAP in equimolar amounts failed to show significant differences in LH and FSH secretion, it is tempting to speculate that a differential release of the two peptides from hypothalamic neurones may change the ratio of circulating gonadotropins observed in certain physiological states².

Prolactin-inhibiting effect of GAP

The inhibitory action of GAP on the secretion of prolactin from pituitary lactotrophs *in vitro* was further investigated in terms of time- and concentration-dependence (Fig. 5). Highly effective concentrations of the peptide (10^{-10} – 10^{-8} M) caused maximal levels of inhibition to 40–45% of the basal secretion after 3–4 h of incubation (Fig. 5a). The gradual decrease in inhibition at longer incubation times could result from degradation of the peptide or may reflect desensitization. Based on these results, we evaluated the prolactin-inhibitory effect as a function of GAP concentration using 4-h incubation periods. The peptide was found to be active at very low concentrations with a half-maximal inhibitory dose value of 2.5×10^{-11} M (Fig. 5b). The maximal degree of inhibition by GAP was comparable with that

caused by 10^{-7} M dopamine. When tested simultaneously at different molar ratios, GAP and dopamine did not act synergistically (data not shown). When applied together with 10^{-7} M TRH, which considerably stimulated prolactin secretion (Table 1), GAP at 10^{-9} M exerted the same magnitude of inhibition as in the absence of TRH (data not shown).

Note that the effective concentration range for the prolactin release-inhibiting effect of GAP is an order of magnitude lower than the corresponding gonadotropin-releasing effect, suggesting that receptors on lactotrophs are more abundant or have a higher affinity for the peptide than receptors on gonadotrophs. As lactotrophs are more abundant in the anterior pituitary than gonadotrophs²⁶, it is likely that most peptide molecules interact with lactotrophs. As prolactin inhibition seems to be the primary action of GAP, the peptide is here classified as PIF.

To assess the physiological importance of GAP in controlling prolactin secretion, serum levels of this pituitary hormone were measured in six rabbits during 13 weeks of immunization with two synthetic peptide antigens corresponding to the amino-terminal and middle regions of GAP. Two animals immunized with unrelated peptide antigens served as controls. GAP-related immunization resulted in increased prolactin levels in all six animals, with most showing dramatic changes, whereas no significant change was seen in the controls (Table 2). GH levels were unaffected in all rabbits. For each animal the increase in prolactin levels could be correlated with the ability of the corresponding antibodies to recognize GAP itself as determined by immunocytochemistry and radioimmunoassay (K.N. *et al.*, in preparation). These data demonstrate that GAP has a dominant role in regulating pituitary prolactin secretion.

Discussion

It has long been recognized that prolactin secretion from the anterior pituitary is predominantly under inhibitory control¹². Although dopamine is known to exert such an inhibitory effect^{24,25,27–30}, there is evidence that dopamine cannot be solely

Fig. 4 Gonadotropin-releasing activity of GAP. LH (a) and FSH (b) secretion from rat anterior pituitary cell culture in the presence of increasing concentrations of GAP (●), GnRH (○) and an equimolar ratio of the two peptides (▲).

Methods. Anterior pituitary cell cultures were prepared as described in Table 1. The indicated concentrations of GAP, GnRH and their mixture were incubated with 5×10^5 cells per ml culture medium in 24-well culture plates for 4 h. Media were removed and assayed by radioimmunoassay. Values are expressed in terms of rLH-RP-2 (a) or rFSH-RP-2 (b) in ng per 5×10^5 cells. Each point represents the mean value of three independent cell cultures in which experimental points were obtained from four parallel culture wells of which duplicate samples were assayed by radioimmunoassay. Vertical bars, s.d. ED_{50} value of LH release induced by GAP was calculated to be 2.05×10^{-9} M with 95% confidence limits: lower, 1.02×10^{-9} M; upper, 7.05×10^{-9} M. ED_{50} value of FSH release induced by GAP was 5.02×10^{-10} M; lower, 9.95×10^{-11} M; upper, 1.18×10^{-9} M.

responsible for overall prolactin inhibition^{31,32}. The existence of a prolactin-inhibitory factor of peptidic nature has been invoked, but such a factor has not yet been characterized from hypothalamic extracts. Attempts to isolate hypothalamic PIF have shown that the areas containing dopamine-free PIF activity were located in the mediobasal hypothalamus and the organum vasculosum lamina terminalis³², regions that have many GnRH-producing and -secreting neurones³. Earlier purification studies from porcine and ovine hypothalamic tissue allowed for size estimates for this activity of $M_r < 8,000$ (refs 32–34).

Fig. 5 Prolactin release-inhibiting effect of GAP. a, Prolactin secretion in the presence of 10^{-11} M (○), 3×10^{-11} M (□), 10^{-10} M (●), 10^{-9} M (■) and 10^{-8} M (▲) concentrations of GAP as a function of incubation time. Secretion is expressed as % of uninhibited basal levels. b, Prolactin secretion from rat anterior pituitary cell cultures in the presence of increasing concentrations of GAP (●) and dopamine (□). Control value without additions is shown by (○).

Methods. Anterior pituitary cell culture from female Sprague-Dawley rats were prepared as described in Table 1 legend. a, Different concentrations of GAP were incubated with 5×10^5 cells per ml medium for 6 h. Samples (20 μ l) of the media were removed at the indicated time points and assayed for prolactin. Values are expressed in terms of rPLR-RP-2 reference protein (National Pituitary and Hormone Program). Points are means of four parallel culture wells from which media aliquots were measured by radioimmunoassay in duplicate. Vertical bars, s.d. b, Indicated concentrations of GAP and dopamine were incubated with 5×10^5 cells per ml medium in 24-well culture plates for 4 h when media were removed and assayed by radioimmunoassay. Points are means $\pm$ s.d. of five independent cell cultures in which experimental points were obtained from four parallel culture wells of which duplicate samples were assayed by radioimmunoassay. Basal levels were determined from eight parallel wells in each culture. The curve shown for GAP was obtained by nonlinear fitting.

Using a different approach, we have here presented a peptidic PIF whose activity on lactotrophs is inhibitory for prolactin secretion at physiological concentrations and whose size and site of synthesis are as expected for the hitherto elusive hypothalamic PIF. This peptide of 56 amino acids was first described as the GAP located on a human placental GnRH precursor protein⁸. The amino-acid sequence for this precursor was deduced solely from the nucleotide sequence of a very rare cDNA species isolated twice from a cDNA library of $\sim 1.5 \times 10^6$ independent clones derived from human placental mRNA. The

Synthetic peptides were conjugated to soybean trypsin inhibitor by *N*-(maleimidobutyryloxy) + succinimide and injected intramuscularly into female rabbits at 0, 3, 5, 7, 10 and 13 weeks according to general procedures of immunization⁵⁵. Blood samples were taken at the indicated time points and assayed for prolactin and GH as described in Table 1. Values in ng ml⁻¹ are expressed in terms of rPRL-RP-3 reference protein and were obtained from duplicate determinations. ND, not done.

prediction of the amino-acid sequence of this peptide, and hence the elucidation of its pituitary function, was possible starting from a few grams of tissue, reflecting the use of recombinant DNA techniques in neuroendocrinology.

In this study we have used the complete 56-amino-acid carboxy-terminal peptide from pro-GnRH. Note, however, that the actual secreted form of this peptide into the hypothalamo-hypophyseal portal circulation is yet to be identified. The carboxy-terminus of GAP is Lys-Lys-Ile (Fig. 1), which may represent an enzymatic processing site giving rise to a 53-amino-acid form, yet a similar sequence at the carboxy-terminus of β -endorphin seems to be unprocessed³⁵. Although there is no further pair of basic amino acids in the molecule, the possibility that shorter fragments arise by cleavage at single basic amino acids cannot be excluded. However, the high potency of GAP suggests that the complete 56-amino-acid peptide is the secreted form and is required for full activity, illustrated by the case of GRF^{22,23}. This concept is also supported by our finding of highly elevated prolactin serum levels in rabbits immunized with synthetic peptide antigens corresponding to both the amino-terminal and the middle regions of GAP covering ~40 of the 56 amino-acid residues. Both synthetic peptides had negligible prolactin release-inhibitory activity *in vitro* (K.N. *et al.*, in preparation).

The fact that a prolactin-inhibiting peptide shares a precursor with GnRH suggests a new model for the hypothalamic control of gonadotropin and prolactin secretion. According to this model, the secretion of these pituitary hormones is coupled through the influence of the two hypothalamic peptides, GnRH and PIF, produced from a single precursor molecule expressed from a unique gene in a population of hypothalamic neurosecretory cells. Because of the differential actions of these peptides, our model predicts that gonadotropin and prolactin levels are inversely related. Thus, when hypothalamic neurones are triggered to secrete GnRH and PIF in a regular episodic pattern, circulating gonadotropin levels will be elevated and prolactin levels repressed. Conversely, irregular firing of the neurosecretory cells and low output of GnRH and PIF result in low gonadotropin and high prolactin release from the anterior pituitary. Whereas the former situation is predicted to occur during reproductive competence, the latter should govern lactation after parturition.

It is well understood that the control of PRL secretion is more complex than is suggested by the action of GAP, due to the influence of additional hypothalamic and extrahypothalamic factors on lactotrophs (see ref. 64 for review). Thus, for example, the co-surge of prolactin and LH found in certain physiological states could result from the overriding effect of prolactin-releasing factor(s)⁶⁵ and/or the stimulation of lactotrophs by factor(s) from GnRH-primed gonadotrophs⁶⁶. However, a wealth of physiological and biochemical evidence supports our model of a central concerted and inverse regulation of LH/FSH and prolactin by the concerted action of the two peptides derived from the GnRH precursor. Indeed, the early recognition of

concomitant inverse changes in gonadotropin and prolactin levels led to the belief that stimulation of gonadotropin release and inhibition of prolactin secretion might be two activities of the same molecule^{12,33}. Thus, suckling stimulates prolactin release but inhibits gonadotropin secretion, both effects being mediated by the hypothalamus^{36,37}. Reproductive disorders such as hypogonadism and amenorrhoea are often associated with hyperprolactinaemia, when pulsatile GnRH secretion is disturbed and low while prolactin is under insufficient inhibition³⁸⁻⁴⁰. The feedback action of oestradiol on the hypothalamus acutely increases prolactin and decreases LH secretion^{41,42}. The ontogeny of the hypothalamo-pituitary-gonadal system in humans and sheep is critically timed and correlates with prolactin secretion⁴³.

The first step is the development of the hypothalamo-hypophyseal GnRH-LH axis followed by the development of the negative feedback circuit via the hypothalamus from the gonads. The first appearance of the negative feedback effect of oestradiol on LH and FSH secretion on the 105th day in the ovine fetus has been found to be concomitant with an increase in prolactin secretion⁴⁴, evidence which is in good agreement with our model.

Opiates inhibit the secretion of GnRH⁴⁵ and the opiate antagonist naloxone increases LH and FSH levels with a concomitant reduction of prolactin secretion^{46,47}. A transplantable prolactin-secreting tumour was found to develop and act through the hypothalamus by inhibiting GnRH release paralleled by high prolactin output⁴⁸. In this study, low levels of LH and FSH were associated with very high prolactin levels despite increased portal blood levels of dopamine. Furthermore, γ -aminobutyric acid (GABA) displays PIF activity and an antagonist of GABA was found to suppress LH and FSH secretion through blocking GnRH output from the hypothalamus⁴⁹. Such GABAergic neurones are oestrogen-receptive and reside in the medial pre-optic/anterior hypothalamic area also controlling LH and FSH secretion⁵⁰.

In conclusion, a tightly coupled regulation of pituitary gonadotropin and prolactin secretion occurs, manifested through the hypothalamic production of a prohormone generating the two hypophysiotropic hormones GnRH and PIF. The fact that the same prohormone is synthesized in extrahypothalamic brain areas and in gonadal tissue suggests that GAP has additional central and paracrine functions involved in the regulation of reproduction.

We thank the Genentech DNA synthesis group for the oligodeoxynucleotides used in this study, Doug Smith and Joel Hayflick for help with plasmid DNA preparations and DNA sequence analysis, William Henzel and Henry Rodriguez for help in peptide analysis, John Burnier for synthetic peptides, and Jeanne Arch for help in preparing this manuscript. We also thank the National Pituitary and Hormone Program (NIADDK) for providing materials for radioimmunoassay. This work was supported by Genentech, Inc. and grants CA 16417 (NIH) and INT 8217148 (NSF) to J.R.

Only 10 different V_{β} gene segments were found when the sequences of 15 variable (V_{β}) genes of the mouse T-cell receptor were examined. From this analysis we calculate that the total number of expressed V_{β} gene segments may be 21 or fewer, which makes the expressed germline V_{β} repertoire much smaller than that of the immunoglobulin heavy-chain or light-chain genes. We suggest that β -chain somatic diversification is concentrated at the V_{β} - D_{β} - J_{β} junctions.

BOTH the T-cell receptor and the immunoglobulins are heterogeneous cell-surface glycoproteins that can recognize many antigens¹⁻³. It is clear from genomic analysis that they share similar strategies for diversification. T-cell receptor molecules are composed of α - and β -chains, each of which, like the immunoglobulin chains, is divided into variable (V) and constant (C) regions¹⁻³. The V regions together form the antigen-binding domain. The β -chain genes of the mouse are the most thoroughly studied T-cell receptor genes. Like the immunoglobulin genes, they are divided into separate V_{β} , diversity (D_{β}) and joining (J_{β}) gene segments that are assembled by recombination during T-cell development to form a V_{β} gene that is associated with either of two constant ($C_{\beta}1$ and $C_{\beta}2$) genes⁴⁻⁸. There are six functional J_{β} gene segments clustered just upstream of each C_{β} gene⁴⁻⁶ and two D_{β} gene segments, $D_{\beta}1.1$, upstream of the $J_{\beta}1$ cluster, and $D_{\beta}2.1$, upstream of the

$J_{\beta}2$ cluster^{7,8}. The total number of V_{β} gene segments is unknown. Like immunoglobulins, the T-cell receptor β -chain has at its disposal three sources of diversity: a multiplicity of germline gene segments⁴⁻⁹; combinatorial diversity through the assembly of different V, D and J segments^{4,9-11}; and somatic mutation^{9,11}. Immunoglobulin genes have three sources of somatic mutation: junctional flexibility at the sites of gene-segment joining¹²⁻¹⁴; the addition of random nucleotides to either side of the D-gene segment in the process of joining (N-region diversity)¹⁵; and somatic hypermutation^{16,17}. It is known that β -chain genes use the first two processes but may not use the third^{4,7-9,11}.

T-cell antigen recognition differs from that mediated by immunoglobulins in that T cells must recognize antigen in the context of a cell-surface molecule encoded by the major histocompatibility complex (MHC), a phenomenon termed MHC restriction^{18,19}. T-cytotoxic (T_C) cells, which are capable of killing virus-infected and tumour cells, are mainly restricted by class I gene products of the MHC²⁰. T-helper (T_H) cells, which are capable of enhancing B- or T-cell responses, are mainly

† Permanent address: Department of Microbiology/Immunology, Northwestern University, Chicago, Illinois 60611, USA.

We determined the nucleotide sequence of eight V_β genes obtained from cDNA libraries that were constructed from thymus cells, the T_H hybridoma 1.9.2 specific for the cytochrome *c* peptide AmDASp (ref. 22) and a functional T_C -cell line specific for MHC alloantigens. The sequence of these V_β genes and seven additional V_β genes taken from the literature were then compared (Fig. 1a, Table 1)^{4,9,11,23,24}. Of the 15 V_β genes analysed, 6 are from T_H cells, 2 from T_C cells, 6 from thymocytes and 1 from a T-cell tumour (Table 1). The antigen/MHC specificities of the functional cells are listed in Table 1. The specific functions and antigen/MHC specificities of the T-cell tumour and the cells that generated the thymocyte-derived V_β genes are unknown. As 99% of thymocytes do not migrate out

Fig. 2 Southern blot analysis of mouse germline DNA using probes from five different V_β gene segment subfamilies. BALB/c mouse liver DNA was digested with *Eco*RI ($V_\beta 1$, $V_\beta 4$, $V_\beta 5$ and $V_\beta 8$) or *Bam*HI ($V_\beta 2$). 10 μ g of each DNA digest was electrophoresed on a 0.8% agarose gel and transferred to nitrocellulose. Blots were hybridized with one of five ^{32} P-labelled V_β gene segment probes at 65°C in 1 M NaCl, 40 mM Tris, pH 7.5, 10% dextran sulphate, 1×Denhardt's solution, 0.1% SDS and 100 μ g ml $^{-1}$ denatured salmon-sperm DNA. The blots were then washed at 65°C in 0.15 M NaCl, 0.015 M sodium citrate, pH 7.5, and 0.1% SDS. The probes are derived from subclones of each V_β gene segment. The faint 5.7-kilobase (kb) band in the $V_\beta 2$ blot results from contamination of the probe with J_β region sequences.

of the thymus²⁵, some of the thymocyte-derived V_β genes may come from non-functional T cells. The 10 distinct protein sequences of the 15 V_β gene segments are shown in Fig. 1b: there are 10 distinct sequences. For reasons discussed below, the first seven sequences listed in Fig. 1b are designated $V_\beta 1$ –7 and the last three $V_\beta 8.1$, $V_\beta 8.2$ and $V_\beta 8.3$. One V_β gene segment appears three times ($V_\beta 1$), three appear twice ($V_\beta 2$, $V_\beta 3$, and $V_\beta 8.1$) and six appear once ($V_\beta 4$, $V_\beta 5.1$, $V_\beta 6$, $V_\beta 7$, $V_\beta 8.2$ and $V_\beta 8.3$). Moreover, when the sequences of seven additional V_β genes isolated from six T_H cells by our laboratory²⁶ and others are included (J. Gorman, unpublished data; M. Steinmetz, personal communication; A. Fotedar, P. Morinaga, B. Singh, T. Tamaoki and T. Wegmann, personal communication; S. Hedrick, personal communication), 11 different V_β gene segments are found in 22 rearranged genes. Six of the eleven different V_β gene segments appear more than once. Common V_β gene segments occur in functional T cells, thymocytes and

the T-cell tumour BW5147. The repeated use of V_β gene segments in a sample of this size suggests that the repertoire of expressed V_β gene segments is small. If we assume that the V_β gene segments are expressed randomly, the size of the V_β gene segment repertoire can be determined statistically.

If there are L species of V_β gene segments and they are expressed with equal probability and are randomly selected from the pool, then the probability (P) of obtaining an observed result is

$$P(m_1, m_2, \dots, m_N) = \frac{1}{L^N} \frac{L!}{(L-M)! M!} \times \frac{N!}{(1!)^{m_1} (2!)^{m_2} \dots (N!)^{m_N}} \times \frac{M!}{m_1! m_2! \dots m_N!}$$

where m_1 is the number of different species found once; m_2 , the number of different species found twice; m_N , the number of different species found N times; $N = \sum_{i=1}^N m_i$ = the total number of samples analysed; and $M = \sum_{i=1}^N m_i$ = the number of different species found in the sampling. Conversely, given the observed result, the relative likelihood that there are exactly L species in the pool is

$$P(L) = \frac{1}{\sum_{L'=M}^{\infty} \frac{L'!}{L'^N (L'-M)!}} \frac{L!}{L^N (L-M)!}$$

For the data discussed above, $N = 22$ and $M = 11$. By choosing a range of values for L and testing each for the probability of arriving at the value $M = 11$ for $N = 22$, the size of the expressed V_β gene segment family is 21 or less at the 95% confidence level. This estimate of the mouse V_β -gene segment repertoire is much smaller than the mouse immunoglobulin V_H (~100–300) or V_K (~100–300) gene-segment families^{27,28}, but larger than the mouse V_λ (2) repertoire²⁹. However, mouse λ -chains are expressed in only a few per cent of mature B cells, whereas β -chains are expressed in all T_H and T_C cells that have been analysed^{30,31}.

We do not know whether each V_β gene segment is expressed with equal probability in the T-cell population or if the sampling of V_β genes is random. In fact, the relative occurrence of V_β gene segments that we observe can also be explained by the frequent use of a small subset of V_β gene segments. Therefore, a much larger set of V_β gene segments could be expressed infrequently. However, the fact that we find identical V_β gene

† The three members of the $V_\beta 8$ -subfamily are denoted $V_\beta 8.1$, $V_\beta 8.2$ and $V_\beta 8.3$.

‡ So little of the D_β gene segment remains in the rearranged V_β gene that it is impossible to know which D_β gene segment contributed the sequence. ND, not determined.

segments expressed in T cells that differ in their antigen recognition and MHC restriction as well as between functional T cells and unselected thymus cells (Table 1), indicates that the effective repertoire of expressed V_β gene segments is probably very small. Accordingly, a large multiplicity of germline V_β gene segments does not seem to be a major contributing factor in the generation of T-cell receptor diversity.

Single gene subfamilies

Another method of estimating the size of the V_β gene segment repertoire is to determine the number of V_β gene segments in the mouse genome that cross-hybridize with V_β probes. This technique will identify V_β gene segments that have extensive homology with the available V_β gene segment probes, and gives a minimum estimate that can be compared with the predicted number. When this type of analysis was carried out with mouse V_H and V_κ gene segment probes, all the V gene segments fell into one of several distinct multigenic subfamilies^{27,28,32}. In mice there seem to be at least 7 V_H subfamilies ranging in size from 2 to >40 members and at least 5 V_κ subfamilies ranging in size from 2 to >20 members^{27,28,32}. (V gene segments with $\geq 75\%$ similarity have been defined as belonging to the same subfamily³³.) From this analysis it was estimated that the total repertoire of V_H and V_κ gene segments is ~100-300 members for each family^{27,28}.

Table 2 shows the percentage similarity between the 10 different V_β gene segments at the protein and nucleotide level. The nucleotide similarity of the V_β gene segments used by the TB2, TB12 and TB23 V_β genes range from 85 to 92%, indicating they are members of the same V_β subfamily. These V_β gene segments have been designated $V_\beta 8.1$, $V_\beta 8.2$ and $V_\beta 8.3$, respectively (Fig. 1b). The similarities among the remaining V_β gene segments range from 34 to 63%. Therefore, these V_β gene segments belong to different V_β subfamilies, which we have denoted $V_\beta 1$ - $V_\beta 7$. As the expressed V_β gene segment repertoire appears limited, it is important to have a generally accepted nomenclature for these sequences, as used with V_L and V_H subgroups³⁴.

To determine the size of the different V_β subfamilies, Southern blot analysis was performed on mouse liver DNA using DNA probes for the $V_\beta 1$, $V_\beta 2$, $V_\beta 4$, $V_\beta 5$ and $V_\beta 8$ subfamilies (Fig. 2). Three of the V_β probes show a single band, indicating that each V_β gene segment represents a different single-gene segment subfamily ($V_\beta 1$, $V_\beta 2$ and $V_\beta 4$). The $V_\beta 5$ and $V_\beta 8$ subfamilies appear to have two and three members, respectively (Fig. 2). Because the V_β gene segment used by the TB21 V_β gene is the first isolated member of the $V_\beta 5$ subfamily, we have denoted it $V_\beta 5.1$ (Fig. 1b). It has been previously reported that the $V_\beta 1$, $V_\beta 2$, $V_\beta 3$, $V_\beta 6$ and $V_\beta 7$ subfamilies are single genes and that the $V_\beta 8$ subfamily has two members^{9,11,24}. Thus, six different V_β subfamilies with one member, one V_β gene segment subfamily with two members and one V_β subfamily with three members have been identified. Including the additional V_β gene segment characterized by Malissen *et al.*²⁶, there are at least 12 mouse V_β gene segments. This minimum estimate for the size

of the V_β gene segment family falls within the range indicated by the statistical analysis presented above and is consistent with the hypothesis that the V_β gene segment repertoire is small.

The V_β gene segment family with its six single-member subfamilies differs from those of the immunoglobulin V_H and V_κ gene families, each of which contains 5 or more subfamilies with 2-40 or more members^{27,28,32}. Southern blots of DNAs from several rodent species as well as rabbit and human analysed with various V_β probes indicate that the single-member V_β subfamily sequences are less conserved between species than those of the three-member family ($V_\beta 8$)⁹. It has been suggested that this difference reflects selective pressures on the single-copy sequences to diverge rapidly, presumably to accommodate recognition of antigen in a changing MHC context⁹. An *ad hoc* argument for specific, positive selection must then be made to explain the unique conservation of the $V_\beta 8$ subfamily. In apparent conflict with this view is the observation that very little restriction enzyme polymorphism of single copy V_β sequences is seen between mouse strains that have diverged significantly in their MHC genes (B.S.K. and R.K.B., unpublished observations; D. Loh, personal communication). In addition, the inbred SJL mouse has deleted two of the five V_β gene segment subfamilies examined (B.S.K. and R.K.B., unpublished observations; D. Loh, personal communication). This indicates that mice have distinct V_β haplotypes containing different combinations of V_β subfamilies. Hence, an alternative explanation for the lack of V_β -gene segment conservation between species is that the ancestor to mammals contained different V_β haplotypes and during speciation distinct V_β haplotypes were passed on to different evolutionary lines. This model does not require a high rate of V_β gene segment mutation and consistent with the lack of restriction enzyme V_β polymorphism in mice. Additional data on the evolutionary divergence of the V_β gene segments should clarify the explanations for these observations.

It is unclear why single-member subfamilies seem to have arisen exclusively in the V_β gene family. Note that no V_β pseudogenes have been found, whereas at least 30% of V_H gene segments are pseudogenes²⁷. These observations raise a question about the mechanisms that are responsible for retarding the duplicative processes seen in other V gene families.

Diversification mechanisms

Despite the fact that a limited number of V_β gene segments have been identified, all 15 of the V_β gene sequences examined are distinct from one another because of combinatorial and somatic mutational processes (Fig. 1a)^{4,7-11}. The germline, combinatorial and somatic mutation contributions to V_β gene assembly are summarized below.

Germline. The β -chain gene family differs from its V_H counterpart in the apparently limited number of germline V_β and D_β gene segments, the expressed V_β gene segment repertoire consisting of perhaps 21 or fewer members compared with 100-300 germline V_H gene segments. In addition, although we do not know the number of germline D_β gene segments, comparisons

Table 2 Homology matrix of the 10 V_β gene segments

Subfamily	$V_\beta 8.1$	$V_\beta 8.2$	$V_\beta 8.3$	$V_\beta 6$	$V_\beta 7$	$V_\beta 1$	$V_\beta 3$	$V_\beta 4$	$V_\beta 2$	$V_\beta 5$

Numbers above the diagonal designate the percentage similarity of sequences on the x and y axes when compared at the protein level; numbers below the diagonal show percentage similarity at the DNA level.

Fig. 3 The D regions from 15 V β genes may arise from just two D β gene segments. The D regions shown in Fig. 1a and those published previously^{4,9,11,23,24} were aligned to either D β 1.1 or D β 2.1. The regions homologous to either D β gene segment are represented by a straight line. The additional nucleotides flanking the germline D β sequences are presumed to be added by N-region diversity. The D region used by TB12 can be derived from either D β 1.1 or D β 2.1 and is so indicated.

of the D segments found in rearranged V β genes indicates that all could be derived from the two D β gene segments previously identified^{7,8} assuming extensive junctional flexibility and N-region diversification (Fig. 3). The heavy-chain locus, by contrast, has at least 10–20 D H segments³⁵. Finally, there are 12 apparently functional J β gene segments, 6 in each J β gene cluster^{4–6}, compared with 4 J H gene segments^{36–38}.

Combinatorial. Combinatorial joining permits either D β gene segment to be joined to any downstream J β gene segment (6 D β 1J β 1 + 6 D β 1J β 2 + 6 D β 2J β 2 = 18 D β -J β rearrangements). Individual V β gene segments appear to join any D β -J β rearrangements (21 $\times$ 18 = 378 V β genes). The D β 1 and D β 2 sequences are each used approximately half the time in the sample analysed and D β 1-J β 2 joinings occur as frequently as D β 1-J β 1 joinings (3 against 3) (Table 1). Eight different J β 1 and J β 2 gene segments are used, with J β 2 gene segments being used in 11 out of 14 examples. Thus, one would expect individual V β gene segments to join with the J β 1 gene cluster 25% of the time and the J β 2 gene cluster 75% of the time, which is what is found, supporting the contention that the joining of the D β 1.1 gene segment to either J β cluster occurs randomly. However, the J β 2.5 gene segment is used 6 of the 11 times that the J β 2 cluster is used. Whether this bias represents the selective effects of antigen or the mechanisms involved in DNA rearrangement is uncertain.

There may be two additional combinatorial mechanisms. Asymmetrical recognition sequences surrounding the D β gene segments potentially permit V β -J β and D β -D β joinings^{7,8}. Data consistent with the former possibility have been presented³⁹, although the interpretation of these data is difficult because of the possible loss of D gene sequences during V β gene segment rearrangement. As yet there is no evidence for either mechanism; hence, if these joinings do occur, they are infrequent.

Somatic mutation. Junctional flexibility in joining gene segments is illustrated in Figs 1a and 3. One to six extra nucleotides are found at either end of the D gene segments. Interestingly, there appears to be no G/C bias (50%) in this N-region diversification in contrast to that reported for immunoglobulin N-region diversity¹⁵.

The D β gene segments may join to the V β gene segments with equal probability in all three translational reading frames, with

the only requirement being that the D β -J β and V β -D β joinings leave the J β sequence in the proper translational frame (data not shown)⁴¹. In contrast, examination of >75 productively rearranged V H genes indicate that D H -gene segment families show a strong preference for joining in one translational reading frame (85%) (M. Kaartinen and O. Mäkelä, personal communication; T.H., unpublished observations). Presumably this difference arises as a consequence of more rigid structural or selective constraints on the D H as opposed to D β segments.

The somatic hypermutation of immunoglobulin genes occurs late in B-cell development, perhaps on exposure to antigen^{40,41}. By contrast, two V β gene segments expressed in functional T H cells specific for different antigens are identical to the germline sequence^{4,11}. On the other hand somatic variants can arise in alloreactive T cells *in vitro*⁴², although the physiological relevance of this observation is uncertain. We see two nucleotide substitutions and one replacement among the three V β 1, and two nucleotide substitutions and one replacement between the two V β 2 gene segments that have been sequenced (Fig. 1a, b)^{9,23}. As all these V β sequences are derived from different strains of mice (Table 1), these differences may result from polymorphism. No other differences were found and we tentatively conclude, in agreement with earlier workers^{4,11}, that somatic hypermutation, if it exists at all, is much less extensive in V β than in immunoglobulin V genes.

V-region similarities

It has been suggested that both the total diversity and the distribution of variability of V β segments differ from those of immunoglobulin V segments and that this may reflect the additional requirements for MHC recognition⁹. We have analysed the pattern of sequence diversity of the available V β sequences with this in mind.

The percentage similarities at the protein level (Table 2) between the different V β subfamilies ranges from 18 to 53% and 77 to 90% between members of the V β 8 subfamily. It has been suggested that V β segments are substantially more divergent than V H sequences⁹. Although their range extends to a lower value (18%) than that observed so far for known mouse V H segments (34%), or human V H segments (24%) (data not shown), when sampling biases are considered (see below) the maximum variation between different V β segments (82%) does not seem significantly larger than the maximum variation found between immunoglobulin V subfamilies (76%).

In immunoglobulin V regions, most of the sequence variability is clustered within three specific 'hypervariable' regions that form the antigen-binding crevice of antibody molecules^{43–46}. Two of these hypervariable regions are encoded by the V gene segments and the third is found in the V H -D H -J H or V L -J L junction regions⁴⁷. We have compared the pattern of variability of the 10 translated mouse V β gene segments (Fig. 1b) with that of a set representing all the known human V H segments and a set of 18 human V H segments with blocked α -amino groups (Fig. 4). Human V H segments were chosen for comparison because they offer a more random representation of V H sequences than any set of mouse V segments that has been sequenced. This is because mouse V H sequences have been highly selected in comparison with V β sequences in two ways. First, mouse V H sequences are derived mainly from immunoglobulins that recognize a relatively limited number of antigens. Second, for technical reasons, mouse V H sequences are almost exclusively determined from heavy chains with unblocked α -amino groups despite the fact that 80% of mouse serum immunoglobulins have heavy chains with blocked α -amino groups⁴⁸. The blocked human V H sequences, on the other hand, were selected randomly from various tumours and patients with other pathological conditions⁴⁷. We have found that the variability distribution of the mouse V β segments (Fig. 4a) is very similar to the distribution found for the set of human α -amino blocked V H segments (Fig. 4b). The variability distribution of the total set of human V H segments (Fig. 4c) represents a less random sampling than the human α -amino-blocked V H segments for the same reasons

Fig. 4 Variability plot of V_β and V_H segments. Variability at each amino-acid position N is calculated⁴³ as: variability _{N} = no. of different amino acids that occur at N /frequency of most commonly occurring amino acid at N . Hypervariable regions can be defined empirically as a set of residue positions whose average variability is substantially greater than the mean variability of the entire sequence. The sequences used are all those available from the protein information resource of the National Biomedical Resource Foundation and GenBank. *a*, Translated sequence of the 10 distinct V_β gene segments shown in Fig. 1b; *b*, 18 α -amino-blocked human V_H sequences; *c*, 31 human V_H sequences representing sequences blocked and unblocked at the α -amino position.

given for the mouse sequences, and shows a more accentuated variability at the two classically defined hypervariable regions. The total set of human V_H sequences also exhibits a slightly lower background variability, partly resulting from the larger size of the sampling. Thus, it is critical to consider sample size and selection when this type of analysis is conducted. We conclude that the distributions of variability in the V_β and V_H segments are not significantly different from one another. Our results are not consistent with the suggestion⁹ that V_β regions have novel hypervariable regions relative to immunoglobulin V regions.

We have also compared V_β and immunoglobulin V segments by analysing them for two properties believed to reflect important structural features of these molecules, the distribution of β -pleated sheet-forming potential⁴⁹ and the predicted hydrophobicity profile⁵⁰. We find the results of these analyses to be almost identical for mouse V_β , V_H and V_κ segments (Fig. 5). Patten *et al.* have also reported that the β -pleated sheet patterns of several V_β segments conform to that of representative V_H and V_κ sequences⁹. V_β sequences also conserve essentially the

Fig. 5 Secondary structure analyses of V_β , V_H and V_κ segments. *a*, β -pleated sheet potential plots, using the method of Chou and Fassman⁴⁹; *b*, hydrophobicity plots using the scale of Kyte and Doolittle⁵⁰. Solid lines, β ; dotted lines, H ; dashed lines, κ . Analyses in *a* and *b* were based on the average value at each position for 55 V_H regions, 100 V_κ regions and 10 V_β regions.

same group of residues that in immunoglobulins are thought to be important in intra-chain structural interactions (data not shown)^{51,52}. These results strongly support the contention that the general biochemical characteristics and predicted secondary structures of the V_β , V_H and V_κ regions are very similar to one another. Accordingly, we predict that the T-cell receptor and immunoglobulin molecules fold into comparable tertiary structures. Therefore, from the analysis of the sequence variability and structural predictions, we find no evidence for the existence of any fundamental differences in how V_β gene segments can contribute to determinant recognition when compared with immunoglobulin V gene segments. This conclusion is supported by the observation that MHC-restricted antibodies have been raised to influenza antigens⁵³. This observation implies that there need be nothing structurally unique about the T-cell receptor structure and its ability to recognize antigen and MHC-restricting elements.

Antigen/MHC specificity

T cells can recognize a range of antigens similar to those recognized by B cells, but in conjunction with the entire range of polymorphic MHC molecules found in a species. Therefore, the T-cell receptor repertoire is expected to be at least equal to the immunoglobulin repertoire. Our observations suggest that the β -chain genes use fewer V gene segments than do immunoglobulins and that somatic hypermutation is infrequent or even non-existent. On the other hand, the V_β subfamilies exhibit the same overall range of sequence diversity as different V_H subfamilies. Furthermore, the contribution of J_β gene segments is three times that of J_H or J_κ gene segments, and because the D_β gene segments can be used readily in all three translational reading frames, the smaller family size than is seen in

immunoglobulins is at least partially compensated for. Finally, β -chains and immunoglobulins both use junctional flexibility and *N*-region diversification, which are major contributors to the generation of diversity within a specific region of the molecule involved in determinant recognition. Hence, we conclude that the limited number of expressed V_{β} gene segments and the infrequent use of somatic hypermutation does not necessarily reflect a restricted β -chain repertoire. Rather, these observations imply that β -chain somatic diversification is more focused to the 3' portion of the V_{β} gene.

There are three possible explanations for the apparent low frequency of somatic hypermutation of V_{β} genes. First, somatic hypermutation may act in B cells to increase the antigen binding affinity of antibodies rather than to generate a broader range of antigen response^{41,54}. T-cell receptors may not need somatic hypermutation because they may operate with a lower binding affinity due either to a lower affinity requirement for T-cell response or to the stabilizing effect of accessory molecules on the T-cell surface. Second, the current sampling may not include T cells equivalent to secondary-response B cells. Third, somatic hypermutation may have highly unfavourable consequences in T cells. In B cells somatic hypermutation occurs late in development, after antigen stimulation. It is possible that somatic hypermutation does not occur late in T-cell development, after immunocompetent cells have migrated from the thymus, in order to prevent the generation of autoreactive regulatory or cytotoxic T cells in the periphery. Thus, somatic diversification may be restricted to occur early in T-cell development, which allows the thymus to remove autoreactive cells arising from the somatic variation. B cells may not be so restricted because of the strong influence of regulatory T cells⁵⁵, and thus are free to undergo somatic hypermutation later in B-lymphocyte development in response to antigen stimulation.

As Table 1 demonstrates, there is no simple correlation between a particular V_{β} gene segment and distinct antigen specificities or MHC-restricting elements. For example, the $V_{\beta}2$ gene segment is used by a T_H -cell specific for trinitrophenol and the I-A^d MHC molecule (E1) and a T_C specific for the H-2D^d alloantigen (AR1). If the V_{β} and V_{α} regions fold in a manner similar to that of their immunoglobulin counterparts, as is suggested for V_{β} regions by our earlier analysis, then both chains will play a critical role in generating the binding site for antigen plus MHC. Accordingly, there is no reason to believe that either chain will have a particular role in recognizing either antigen or MHC individually.

We thank Marcus Meister for deriving the statistical calculation used for V_{β} gene segment number estimates and help with statistical analyses. We also thank Susan Stone, Debbie Maloney and Marty Garcia for technical assistance, Gerald Siu and Dr Mitchell Kronenberg for helpful advice and stimulating discussion, Drs Nilabh Shastri, Joan Kober, Nancy Costlow, Joan Goverman, Stephen Hunt, Regina Haars, Ulf Landegren and Martha Zuniga for critical comments, and Gwen Anastasi, Connie Katz and Bertha Jones for help in preparing the manuscript. We acknowledge the following sources of support: the Cancer Research Institute (R.K.B.) and the NIH (L.E.H.).

Note added in proof: Recently, the sequences of 15 additional V_{β} genes have been determined (D. Loh, personal communication). When these are added to the 22 existing V_{β} sequences, only 16 different V_{β} gene segments are defined from a total of 37 sequences. These additional data support our hypothesis of a limited V_{β} gene segment repertoire. Furthermore, when these data are included with our own data and analysed for the distribution of variability, hydrophobicity and β -pleated sheet-forming potential, the results are very similar to those presented here.

Ultraviolet continuum variability of the quasar 3C273

T. J.-L. Courvoisier* & M. H. Ulrich†

* Space Telescope European Coordinating Facility, ESO, Karl Schwarzschild Strasse 2, D-8046 Garching bei München, FRG

† European Southern Observatory, Karl Schwarzschild Strasse 2, D-8046 Garching bei München, FRG

Several quasars show an excess of radiation in the ultraviolet over the power law defined by their infrared/optical continuum. Several authors¹⁻⁴ have fitted the infrared to ultraviolet spectrum of these quasars with a combination of a power law component, line emission, blends of Fe II lines, Balmer continuum and a black-body component which dominates the ultraviolet spectrum. We report here the first observations of variability in the ultraviolet spectrum of the quasar 3C273 (redshift, $z=0.158$) as observed by the International Ultraviolet Explorer (IUE)⁵ in the period 1978-84. The flux at $\lambda_{\text{observed}} = 1,675 \text{ \AA}$ increased by 1.25 between April and June 1982, then decreased by a factor 2 between June 1982 and April 1983. The amplitude of these variations and the constancy of the intensity of the Ly α emission line during the same period are indications that the ultraviolet variations are caused by variations of the black body and/or non-thermal components and not by variations of the continuum or blend of lines originating from the broad-line region. The flux variations are accompanied by variations of the spectral shape. We present an interpretation of the observed variability in terms of a discontinuous and variable distribution of the temperature on the photosphere emitting the ultraviolet continuum.

Archived IUE low-dispersion spectra of 3C273 taken between July 1978 and July 1984 have been analysed. These spectra were taken in various programs and were therefore not optimized for a study of the variability. We have retained only the images taken through the large aperture, and which are not overexposed, or only weakly overexposed, at the peak of the Ly α emission line (Table 1).

Standard IUE data reduction, IUESIPS, was performed on the raw data to obtain calibrated spectra from which daily averages (weighted by the exposure time) were made when several spectra on the same date were available. The flux f_ν was binned into 50- $\text{\AA}$ bins although only those bins were retained for which no reseau or emission line could modify the spectrum significantly. Ten bins were selected in the long wavelength (LW) range of IUE between $\lambda_{\text{obs}} = 2,310$ and $2,860 \text{ \AA}$. The FeII multiplets make a small contribution to the flux in all the bins. Wills *et al.*⁶ have studied the quasar-energy distribution in the

range 2,000-5,000 $\text{\AA}$, and find that the FeII spectrum contribution used in the fit of the spectrum of 3C273 does not exceed 0.15 of the total flux at any wavelength. In the short wavelength (SW) range, there are only two bins free of emission lines, centred at $\lambda_{\text{obs}} = 1,275$ and $1,675 \text{ \AA}$, or $\lambda_{\text{rest}} = 1,100 \text{ \AA}$ and $1,446 \text{ \AA}$, respectively.

The sensitivity of the IUE cameras is slowly decreasing with time in a wavelength dependent way^{8,9}. The sensitivity decline of the short wavelength prime (SWP) camera is $<1\% \text{ yr}^{-1}$ for $\lambda < 1,800 \text{ \AA}$ (the region of interest here). For the long wavelength redundant (LWR) camera, the decline has been by $\sim 2.5\% \text{ yr}^{-1}$ for $2,250 < \lambda < 2,550$ and $\sim 1.3\% \text{ yr}^{-1}$ for $\lambda > 2,550 \text{ \AA}$. We have made no correction for this and the error so induced is $<2\%$ for the SWP camera and $<5\%$ for the LWR camera for the period 1982-84. The r.m.s. error on individual flux measurements of optimally exposed spectra is 3.5% for all the three cameras. A further source of error of up to 3% is introduced by the different exposure times used at the different epochs. The r.m.s. of the error resulting from these different sources of error is thus $\sim 5\%$ for the SWP camera and 7% for the LWR camera in the period 1982-84. The LWR fluxes of 1978 and 1979 are overestimated by ~ 10 and $\sim 8\%$, respectively, with respect to the 1982 LWR fluxes, while the SWP fluxes of 1978 and 1979 are overestimated by 5 and 3%, respectively, with respect to the 1982 SWP fluxes.

Figure 1a shows the light curve of 3C273 at $\lambda_{\text{obs}} = 1,675 \text{ \AA}$. The flux is usually near $f_\nu \sim 13 \text{ mJy}$ except in the period April-June 1982 during which it increased from 18 to 23 mJy.

The ultraviolet energy distribution of 3C273 in the period April 1982 to July 1984, on which we concentrate our analysis,

Fig. 1 a, The flux of 3C273 as a function of time averaged over a 50- $\text{\AA}$ bin centred at $\lambda_{\text{obs}} = 1,675 \text{ \AA}$. No reddening correction has been applied. Ordinates in mJy. b, The parameter ϵ represents at each epoch the difference between the SW flux near $1,460 \text{ \AA}$ and the value at $1,460 \text{ \AA}$ of the power law representing the LW spectrum. The values of ϵ have been calculated after a reddening correction, $E(B-V) = 0.05$, has been applied. Ordinates in mJy. c, α_{LW} is the spectral index of the power law representing the spectrum in the LW range after correcting the spectra for reddening $E(B-V) = 0.05$.

Table 1 Short and long wavelength spectra

Date	SW spectra	Exposure (min)	LW spectra	Exposure (min)
15 April 1978	SWP 1,366*	50		
26 May 1978	SWP 1,642*	90		
24 July 1978			LWR 1,886*	50
25 July 1978	SWP 2,099*	50	LWR 1,887*	40
4 May 1979	SWP 5,116*	25		
5 May 1979			LWR 4,454*	40
18 April 1982	SWP 16,790	3 × 40	LWR 13,042	3 × 40
20 April 1982	SWP 16,801	30	LWR 13,055	30
	16,802	30	13,056	30
	16,803	30	13,057	30
27 June 1982	SWP 17,300	15	LWR 13,562	20
	17,301	23	13,563	23
	17,302	27	13,564	22
	17,303	12		
15 April 1983	SWP 19,731	15	LWR 15,739	15
11 July 1984	SWP 23,444	39	LWR 3,757	30

* Reprocessed in 1984 at ESA Villafranca Satellite Tracking Station.

Fig. 2 The spectrum of 3C273 corrected for reddening, $E(B-V) = 0.05$, at five different dates between April 1982 and July 1984. $\times$, 27 June 1982; $|$, 18 and 20 April 1982; $\bullet$, 15 April 1983; $+$, 11 July 1984. The flux values have been averaged in 50-Å bins. In the short wavelength range of IUE, only the bins centred at 1,275 and 1,675 Å are free of emission lines. Blended Fe II multiplets contribute weakly and unevenly to the flux in the 10 long wavelengths bins selected between 2,310 and 2,860 Å. Ordinates in mJy. The two points which at each wavelength represent f_v for 18 and 20 April 1982 are joined by a vertical bar. The points of 18 April are always at the lower end of the bar except at $\lambda_{\text{obs}} = 1,275$ Å.

is shown in Fig. 2. A correction for reddening corresponding to $E(B-V) = 0.05$ has been applied. This value is the reddening in our Galaxy as deduced from observations of H I absorption in the direction of 3C273 (ref. 7). The dereddened spectral shapes discussed below depend on the choice of $E(B-V)$ but the differences between spectral shapes persist whatever the value of $E(B-V)$. The two points which at each wavelength represent f_v for 18 and 20 April 1982 have been joined by a vertical bar. The points of 18 April are always at the lower end of the bar except for the shortest wavelength bin centred at $\lambda_{\text{obs}} = 1,275$ Å. It is not clear whether this systematic difference is real and is part of the increase observed between April and June 1982, but it does represent an upper limit to the error on the reproducibility.

Figure 2 shows that the spectra vary in flux and in shape. Whereas the whole ultraviolet continuum can be reasonably well fitted by power laws of various slopes on most dates, the spectrum in April 1982 definitely cannot, the flux in the SW bins lying well above the extrapolation of the LW spectrum. We emphasize that the power laws are used here as simple, smoothly varying functions with no inflexion point, which, in some cases, provide an acceptable approximation of the data. Over the small-frequency range analysed here they can fit an optically thin synchrotron spectrum or the blue part of a black-body function or a combination of the two.

During the period 1982–84 the intensity of Ly α has not changed appreciably. This is illustrated in Fig. 3 which shows the spectra of 27 June 1982 (thick line) and 11 July 1984 (thin line) in the vicinity of Ly α . The spectra coincide after the 1984 spectrum has been shifted by $+18.0 \times 10^{-14} \text{ erg cm}^{-2} \text{ s}^{-1} \text{ Å}^{-1}$. Excellent theoretical calculations of line intensities in quasars and Seyfert galaxies have been published by several authors. The calculations by Kwan¹³ show that the intensity of Ly α is practically proportional to the value of the ionizing parameter. Moreover, the ratio of the intensity of the iron lines in the interval 2,240–2,650 Å over the intensity of the Ly α line does not increase by more than a factor ~ 2 for an increase by a factor 100 of the ionizing parameter. For this reason we take the large variations of f_v and the constancy of the Ly α intensity as an indication that the changes in 1982–1984 did not originate in the broad line region (line blends or Fe II continuum and free-free, free-bound H continuum) but were caused by variations

Fig. 3 The spectrum of 3C273 near the Ly α emission line. Thick line 27 June 1982 (average of SWP 17,301 and SWP 17,302). Thin line 11 July 1984 shifted by $+18 \times 10^{-14} \text{ erg cm}^{-2} \text{ s}^{-1} \text{ Å}^{-1}$. The continuum in June 1982 is 1.8 times stronger than in July 1984 while the Ly α line has not varied significantly. Ordinates in $10^{-14} \text{ erg cm}^{-2} \text{ s}^{-1} \text{ Å}^{-1}$. No reddening correction has been applied.

of the central black body and/or non-thermal component. The fact that Ly α has not been observed to vary is probably due to a time delay of months between the ionizing continuum source and the broad line gas.

A quantitative appreciation of the change in the spectral shape is obtained by introducing two parameters: (1) the slope, α_{LW} , of the power law fitting the spectrum in the LW range after the reddening correction has been applied. The values of α_{LW} are plotted in Fig. 1c. Although α_{LW} is smallest in June 1982 when the flux is highest the data available do not show a correlation between α_{LW} and flux unlike observations in some Seyfert galaxies, for example, NGC4151 (ref. 10). More numerous data covering a larger range of flux variations might, however, show such a trend. (2) To quantify the discontinuity in the slope of the ultraviolet spectrum occurring at some dates near 2,200 Å we use the parameter ϵ . Let us consider the point which, in the $\log f_v$ versus $\log v$ plot, is at mid-distance between the two points representing the flux at 1,275 and 1,675 Å. Its abscissa corresponds to 1,461 Å. The parameter ϵ is the difference between the ordinate of this point and the value at $\lambda = 1,461$ Å of the power law representing the LW spectrum (and having the slope α_{LW}). Figure 2b gives ϵ calculated from the dereddened spectra. A small value of ϵ means that the whole (dereddened) ultraviolet spectrum can be well represented by a power law. A large value of ϵ suggests the presence of two spectral components varying independently.

The variations of the ultraviolet continuum spectral shape observed in 1982 occurred at a time when the ultraviolet flux was approaching its observed maximum (Fig. 1a). The sparse time coverage of this event and the lack of correlated optical measurements make it difficult to calculate accurately the energy radiated in this 'flare'. The order of magnitude can be estimated assuming that the ultraviolet continuum flux stayed for ~ 2 months at its value of 27 June 1982 which is about twice its value in preceding and following years.

Taking the spectral decomposition of ref. 4, which is based on IUE data of 3C273 of 1978–79, gives an ultraviolet luminosity of $\sim 10^{47} \text{ erg s}^{-1}$. A flare lasting for about 2 months would, therefore, radiate $\sim 5 \times 10^{53} \text{ erg}$ ($H_0 = 50 \text{ km s}^{-1} \text{ Mpc}^{-1}$).

We note that the discontinuity in the ultraviolet spectrum at $\lambda \sim 2,200$ Å is not reproduced well by any published combination of various continua and smooth black-body spectra. This discontinuity, which is most apparent in April 1982, suggests that, in addition to the black-body component at 20,000–26,000 K recognized by several authors^{1–4}, there could be a hotter component with $T \sim 35,000$ –40,000 K covering a smaller area than the

20,000 K component. One can speculate that the spectral variations of April–June 1982 are due to an increase of the flux emitted by the hotter component (increase in area) probably accompanied by a smoothing of the temperature distribution. The hot component may result from the sudden heating of the inner part of an accretion disk. Another speculative possibility is the explosion of a supernova in a large cluster of stars coinciding with the central source. In the wind and shock model¹¹, this would cause a heating of one part of the ultraviolet photosphere.

The flare seen in the ultraviolet should manifest itself in other regions of the spectrum. Note that a flare in the millimetre-infrared was observed in 1983, although with a significantly lower energy, 10^{45} erg (ref. 12). It is uncertain whether the two flares are related. This points to the importance of continuous broad-band monitoring of this type of sources, as the observation of a time delay between the flaring at different wavelengths would give precise information on the relations between the different physical components.

The presence of flares in different parts of the spectrum makes the spectral decompositions attempted^{1–4} very dependent on the epochs of the measurements at different wavelengths. This effect has yet to be taken into account.

We thank Dr E. Tanzi for supplying the 1984 data and the staff of the ESA Villafranca Tracking Station for reprocessing some spectra. T.J.-L.C. is affiliated to the Astrophysics Division, Space Science Department, European Space Agency.

Discovery of Jupiter's 'gossamer' ring

Mark R. Showalter*, Joseph A. Burns*,

Cornell University, Ithaca, New York 14853, USA

†NASA/Ames Research Center, Moffett Field, California 94035,
USA

Jupiter's ring system has previously been described as being composed of a 'bright' narrow ring and an interior, vertically-extended halo^{1,2}. The one image which reveals this morphology most clearly is Voyager 2's parting shot of the Jupiter system, a wide-angle (WA) view of the ring ansa in forward-scattered light (FDS 20693.02). The bright ring is plainly visible, and the halo appears after slight contrast enhancement. By further enhancement of this image we have discovered an additional ring, which is far fainter than either of the (already faint) components previously identified, extending to a radius of 210,000 km.

The ring is visible as the blue-green stripe extending outward from the bright ring in Fig. 1. Although this feature has a mean intensity of only one-half the overall image noise level, it covers such a large area ($\sim 3 \times 10^4$ pixels) that its integrated signal-to-noise ratio is ~ 110 . Previous WA frames were checked to verify that this is not a ghost image, such as are occasionally visible in Voyager data. The lack of systematic variations of this form in any other Voyager images, as well as the consistency of this feature's morphology with a flat circular ring in Jupiter's equator,

Fig. 1 An enhancement of Voyager image FDS 20693.02, shown black-and-white above and colour on the cover. Here discrete colours of the spectrum have replaced a range of the darkest shades of grey in the image. The newly-discovered 'gossamer' ring is visible as a blue-green stripe running outward from the bright ring (in white). The halo (outlined in red-yellow) rises at the bright ring's inner edge, and extends vertically above and below the ring.

safely rule out the possibility that the stripe is a quirk of the Voyager vidicon.

This particular image has already received extensive scrutiny^{2,3} so it may seem surprising that the ring has been overlooked. Raw Voyager images receive extensive reprocessing on the ground, which includes the subtraction of a 'dark current', or image of dark sky, to model the null response of the vidicon. Previous versions of this frame were processed with an inappropriate dark current; this introduced a strong intensity gradient to the dark sky regions of the image, which masked this very subtle feature. We first noted the ring after subtracting an empirical fit to the background of the flawed image data, but found it easily once the image had been reprocessed with an updated dark current.

Only one additional Voyager image captures this ring with tolerable signal-to-noise ratio. The final frame (FDS 20693.01) of a narrow-angle (NA) mosaic accidentally fell beyond the bright ring's ansa, and so captured a piece of this faint structure (Fig. 2). However, the ring contributes only a smooth intensity gradient to the restricted NA field of view, which would have been impossible to interpret unequivocally without the context of the WA frame. Despite some uncertainty in this image's true dark current, it is compatible with the presence of the exterior ring⁴.

In retrospect, the additional ring was hinted at in earlier Pioneer 10 and 11 data. Pioneer 10's meteoroid impact detector recorded at least one event near ring plane crossing at 206,000 km (refs 5, 7), well outside the bright ring but within the ring described here. Since the instrument locks out additional detections for 80 min following an event, the actual number of impacts

Fig. 2 A comparison of the wide-angle (WA) and narrow-angle (NA) frames. *a*, A portion of the WA frame (FDS 20693.02), contrast-enhanced to show the gossamer ring. The rectangle outlines the corresponding NA field of view. *b*, The NA image (FDS 20693.01), using the same contrast enhancement.

during ring plane crossing is not known. Also, the Pioneer 11 charged particle absorption data, which first detected the bright ring⁶, have never been completely unravelled (W. Fillius, personal communication) but may require additional absorbers between Amalthea and the ring.

Since this 'gossamer' ring is only present at 0.5σ in the WA image, extracting its properties may only be accomplished by averaging over large numbers of the available pixels. Figure 3 is a radial profile of the ring, generated by averaging pixel intensities along contours of constant orbital radius. It shows that the ring decreases in intensity rather uniformly with radius; most of it lies inside the orbit of Amalthea, though some material extends out to 210,000 km, and perhaps to the neighbourhood of Thebe. Its overall mean brightness is $\sim 5\%$ that of the main ring. The profile's only notable feature is a $\sim 20\%$ enhancement centred at $160,000 \pm 2,000$ km, quite close to synchronous orbit (160,200 km). This bulge is significant at the 4σ level; in fact, it was first observed visually in the image, and only later found to fall on top of a special orbit. This unresolved feature is 5,000-km wide in the scan, but may actually be much narrower and brighter.

The profile of Fig. 3 is produced assuming that the ring is azimuthally symmetric, relatively thin and confined to the equatorial plane. A firm upper limit of 4,000 km may be placed on the ring's vertical extent from the width of the observed stripe at Voyager's shallow viewing angle (a mere 2° from the ring plane); although not severely constrained, this ring is distinctly thinner than the halo. For a ring ≥ 200 km thick, lines-of-sight from Voyager would sample a significant range of orbital radii through the ring plane. In this case, vertical structure would be confused with radial structure, and the profile would be in error. However, the synchronous feature must be < 200 km thick to be consistent with its width in the profile.

The ring shows some evidence for a variation in brightness with scattering angle θ over the limited range sampled. Intensity at constant orbital radius increases by nearly a factor of two between $\theta = 7^\circ$ and 6° , suggesting diffraction by grains of radius $r \approx 1.5 \mu\text{m}$ (Fig. 4). Although this strongly implies the presence of micrometre-sized grains, as in the main ring^{2,4}, it is not

possible to exclude the presence of either larger or smaller particles based on such a tiny range of θ (ref. 1). If the constituent particle size distribution is the same as that in the bright ring, then this ring's normal optical depth $\tau \approx 10^{-7}$, which is comparable to that of Saturn's E ring, another ring known for its small grain population¹. This value is compatible with $\tau \geq 10^{-8}$, determined from the Pioneer 10 impact detection near the ring's outer boundary, and applying only to particles larger than $r \approx 6 \mu\text{m}$.

We have failed to detect this ring in the three available backscattered views of the main ring's terminus (FDS 16368.19, 20630.52, 20630.53), despite averaging over many pixels; in these images, the exterior ring must be $< 1\%$ as bright as the main ring. This limit is smaller than the rings' forward-scatter intensity ratio of $\sim 5\%$, which suggests that the gossamer ring contains relatively fewer particles large enough ($r \gg 1 \mu\text{m}$) to backscatter efficiently⁴.

The dominant evolutionary process acting to move jovian ring material is plasma drag¹. This force arises from collisions with plasma, which is tied to the planet's rotating magnetic field; it evolves material away from synchronous orbit, either inward or outward, on timescales of $\sim 10^{3 \pm 1}$ yr for micrometre-sized grains. The dominant destruction process, sputtering, acts on similar timescales for these tiny grains¹.

Given such brief lifetimes, ring material must be continually replenished from some source for the ring to remain visible today. The alternative, that the ring is quite young, implies that our detection of it was an exceedingly unlikely event. The satellites Amalthea and Thebe, embedded near the ring's outer edge, are obvious candidates for source bodies; micrometeoroids impact their surfaces, injecting dust into the ring system¹. Due to its larger escape velocity, Amalthea is only $\sim 1/10$ as effective in this role as Adrastea, which contributes to the bright ring^{1,4}. However, Amalthea and Thebe's ejecta should evolve outwards under plasma drag, and so cannot fully explain the gossamer ring.

Unseen bodies provide a plausible alternative source, and these must extend across the synchronous orbit for the ring to also appear on both sides. Since sputtering and plasma drag act

Fig. 3 A radial profile of the external jovian ring. The vertical axis is in non-dimensional units of $\tau \omega_0 P$, where τ is normal optical depth, ω_0 is single-scattering albedo and P is the phase function at scattering angle θ . This quantity is directly proportional to measured intensity, but eliminates various projection effects⁴.

on comparable timescales, we expect a steady decrease in brightness with distance from any source region. This may account for the ring's observed linear decay beyond synchronous orbit, implying that the source bodies are confined to a much narrower radial region than are the visible grains.

The bright feature at synchronous orbit appears surprising at first, since plasma drag drives material away from this location, not towards it. However, here the ring material and plasma corotate, so the plasma drag force vanishes. Hence, material injected into the ring at this orbit will evolve away more slowly (probably inward under the weak Poynting-Robertson drag force¹) than that introduced elsewhere. If the source body population straddles synchronous orbit, then this brightness enhancement is to be expected.

Another mysterious aspect of this ring is its limited vertical extent, <4,000 km. The halo is thickened by perturbations from Jupiter's inclined magnetic field, acting on its tiny, charged grains^{1,2,8}; the same processes should also be acting in this ring. The one important difference is the strength of the magnetic forcing. The dipole field component in the exterior ring is smaller by a factor of ~3, while higher-order moments are reduced even further. At the same time, grain velocities with respect to the

corotating field are smaller here, close to synchronous orbit. It is consistent with this trend that strong Lorentz resonances seem to have a major role in the halo⁸, but are not present in the gossamer ring. These circumstances combine to reduce the magnetic perturbations, and hence the ring's vertical extent, by a factor of at least 10 compared with the halo. This places the ring's thickness within its measured upper limit.

Although this gossamer ring remains enigmatic, it may at least have a dynamical counterpart at Saturn. A very faint outward extension to Saturn's A ring has been discovered by statistical analysis of the Voyager 2 photopolarimeter stellar occultation data⁹. Like its jovian analogue, it extends from a much brighter ring (Ring A) outwards to the vicinity of a satellite (Atlas), while decreasing continuously in optical depth. Its mean τ is ~2% of the outer A ring value. However, in its radial width (~900 km) and overall optical depth (~0.01), this ring is very different from the faint outer ring at Jupiter. Additional material at much lower optical depths, identified using image processing techniques similar to those described herein, fills the entire region between the A and F rings¹⁰. Whether these structures truly have a common dynamical basis is unknown, but surely searches should be made for similar material at Uranus.

We thank G. Garneau, C. Hansen, and especially S. A. Collins for help with the data processing, and W. Fillius for helpful discussions. M.R.S. and J.A.B. were supported in part by NASA grant NAGW-310.

High time-resolution observations of periodic frictional heating associated with a Pc5 micropulsation

G. Crowley, N. Wade, J. A. Waldock, T. R. Robinson & T. B. Jones

Department of Physics, Leicester University, University Road, Leicester LE1 7RH, UK

Fig. 4 Variations in ring intensity with scattering angle θ , measured at constant radius. Despite the point scatter, a brightening trend is revealed; a straight-line fit to the data yields a slope of $0.7 \pm 0.1 \text{ mag deg}^{-1}$. Phase functions for particles of size parameter X are shown for comparison⁴, where X is defined as the ratio of particle circumference to wavelength ($0.5 \mu\text{m}$). Δ , Near arm; $\blacksquare$, far arm.

Geomagnetic micropulsations are fluctuations of the Earth's magnetic field on time-scales ranging from a few seconds to several minutes and with amplitudes varying between a few and several hundred nanotesla. In the inner magnetosphere, where the Earth's magnetic field lines are closed, the oscillations can adopt a standing wave pattern with a scale size comparable to the dimensions of the magnetospheric cavity. These hydromagnetic waves constitute one of the primary mechanisms for the transfer of energy from the outer regions of the magnetosphere to the high-latitude ionosphere during geomagnetic substorms. In the ionosphere, Joule heating is thought to be the dominant damping process for the pulsations and the rate of energy dissipation during a typical event¹ is of the order of 10^9 W . By means of the EISCAT (European Incoherent Scatter) radar facility it has been possible to measure directly the ionospheric ion-temperature and ion-velocity fluctuations during a micropulsation. The relationship predicted by the theory of Joule heating for these two parameters is confirmed in detail by the high time-resolution results reported here.

Fig. 1 Perturbations of *a*, the horizontal geomagnetic component, *H*, and *b*, declination, *D*, at Tromsø, Norway during a Pc5 micropulsation on 30 November 1982; *c*, ion velocity fluctuations derived from EISCAT data and resolved in the eastward-perpendicular direction.

Frictional heating in the thermosphere arises due to relative motion between the neutral and ionized particles. The electric field associated with a micropulsation drives the ions whilst the neutral motion remains essentially unchanged. Assuming that the neutral particles are stationary, theory predicts that Joule heating should produce an ion-temperature enhancement, ΔT_i , proportional to the square of the ion-velocity^{2,3}, v_i , according to

$$\Delta T_i = m v_i^2 / 3k \quad (1)$$

where m is the molecular mass of the neutral gas and k is Boltzmann's constant. This steady-state relationship is applicable to pulsation events since the time-scale of heating is much shorter than that of changes in the temperature and velocity of the neutral atmosphere.

On 30 November 1982, EISCAT was operating in the CP- ϕ mode, in which the Tromsø beam was directed along the Earth's magnetic field and the beams of the remote receiving antennas at Kiruna and Sodankylä intersected the Tromsø beam at an altitude of 312 km. Hence the full vector of plasma velocity in the common scattering volume could be determined⁴. At about 1215 UT a micropulsation occurred and large fluctuations in the ion-temperature and velocity were detected at Sodankylä. The ion-temperature fluctuations were ascribed to frictional heating^{5,6} but the time resolution of their data (200 s) was insufficient to establish a detailed correlation with the velocity perturbations. High time-resolution (30 s) data from all the EISCAT sites indicate that the ion-temperature fluctuations are precisely correlated with a rectified form of the ion-velocity perturbations, as predicted by theory (equation (1)).

The perturbations in the *H* (horizontal) and *D* (declination) components of the geomagnetic field at Tromsø, Norway, during the micropulsation are reproduced in Fig. 1*a* and *b*, respectively. The impulsive onset of the event coincides with a transient compression of the dayside magnetosphere at 1211 UT. This sudden commencement was not followed by a magnetic storm and the micropulsation was quickly damped. The pulsation period was ~ 9 min, hence the event is classified as a Pc5 micropulsation, although the wave amplitude was unusually large (~ 100 nT).

The ion velocity calculated from the EISCAT data and resolved perpendicular to the geomagnetic field also displayed large fluctuations with periods of 9 min during the pulsation (Fig. 1*c*), which were well correlated with the magnetic *H*-component variations. The amplitude of the eastward velocity component, V_{PE} , was 1 km s^{-1} , about 5 times that of the northward component.

Fig. 2 Ion-temperature fluctuations scaled to the mean at each altitude, measured by EISCAT for altitudes of 130–312 km. The micropulsation event commenced at about 1215 UT.

Fig. 3 *a*, Ion-temperature enhancements above the ambient value of 1,100 K, for an altitude of 312 km; *b*, ion-temperature perturbations derived from equation (1) in conjunction with ion velocities measured by EISCAT.

Transient enhancements of the ion temperature occurred at all heights in the range 130–312 km during the pulsation (Fig. 2). The high time resolution (30 s) of the data presented here permits the following interesting feature to be identified. The ion-temperature fluctuations are correlated precisely with a rectified form of the velocity perturbations during the micropulsation. This feature is illustrated in detail, for an altitude of 312 km, in Fig. 3 which compares the measured temperature variations (Fig. 3*a*) with theoretical predictions, using the measured velocities in conjunction with equation (1) (Fig. 3*b*). The ambient ion temperature at 312 km was $\sim 1,100$ K and the calculations reproduce temperature enhancements of between 400 and 1,000 K. Agreement between the two curves of Fig. 3 may be improved by taking the neutral wind velocity into account. However, this is likely to be $\sim 100 \text{ m s}^{-1}$, a fraction of the large ion velocities, and the correction is therefore small. The mean molecular mass employed in these calculations, $m = 17.1$ at 312 km, was derived from the US Standard Atmosphere, 1976. Similar excellent agreement between predicted and measured temperature perturbations was also obtained for other altitudes when appropriate molecular masses were employed in the calculation.

The ionospheric conductivity was approximately constant during the micropulsation⁵ and there is no correlation between the F-region electron and ion-temperature fluctuations during the event. Particle precipitation is not, therefore, responsible for the ion-temperature enhancements. On the contrary, the magnitudes of the measured temperature and velocity perturbations are quantitatively consistent with the expression given by equation (1) and these preliminary results thus provide indisputable evidence that large transient variations in ion temperature measured by the EISCAT radar during a Pc5 micropulsation are due to frictional heating. The results also support the hypothesis that ionospheric Joule heating is the primary damping mechanism for micropulsations.

We thank the staff of the EISCAT facility for the observations made during the Common Programme, and S. Berger and A. Brekke of the Auroral Observatory, University of Tromsø for

providing magnetograms. EISCAT is an international facility supported by the research councils of Finland (SA), France (CNRS), Germany (MPG), Norway (NAVF), Sweden (NFR), and the UK (SERC).

A 450-year drought reconstruction for Arkansas, United States

D. W. Stahle, M. K. Cleaveland & J. G. Hehr

Department of Geography, University of Arkansas, Fayetteville, Arkansas 72701, USA

A 450-year reconstruction of the June Palmer Drought Severity Index¹ (PDSI) has been derived for Arkansas using annual tree-ring chronologies from selected old-growth baldcypress trees (*Taxodium distichum* (L.) Rich.) found in floodplain swamps. This is the first palaeoclimate reconstruction achieved with baldcypress, and is some 150 years longer than any previous dendroclimatic estimate for eastern North America. The reconstruction is characterized by substantial fluctuation in the intensity and duration of past wet and dry spells, and is well verified against independent climate data. While there has been some very limited previous use of wet site species for dendrochronology^{2,3}, this is the first verified climate reconstruction based exclusively on a swamp-grown species. Several 500-800-year-long baldcypress chronologies are under development, and some may be extended into mid- to late-Holocene times with tree-ring records from preserved subfossil cypress logs⁴.

The extremely wet habitat of baldcypress contrasts sharply with the classic semi-arid tree-ring sites where dendroclimatology was first developed. Like many arid site trees, however, the radial growth of baldcypress and some other wet site species⁵ may be slow and highly variable, which may reflect, in part, the less than optimal excessive moisture conditions. The frequently inundated, alluvial nature of the cypress habitat also favours the rapid burial and long-term preservation of fallen cypress logs, a critical precondition for the development of millennia-long baldcypress tree-ring chronologies.

Baldcypress logging began in the late eighteenth century and reached a maximum around 1900 (ref. 6) but small relict stands of old-growth cypress remain scattered throughout its native range in the southeastern United States. We have discovered old, datable, and climate sensitive baldcypress on both blackwater and brownwater river systems⁷ (that is, streams characterized by organic and inorganic chemical loads, respectively), but have encountered dating difficulties with baldcypress from certain habitats near the southern limits of its range. Individual cypress >850-yr old have recently been sampled, and while older trees⁸ probably exist they have yet to be documented adequately. We have completed four baldcypress chronologies for Arkansas (Fig. 1), and include the three longest series in this analysis. These tree-ring sites have not been heavily disturbed and are not subject to high pollution levels, but all are located in drainage basins with extensive agricultural development.

Increment cores were extracted above the often pronounced root buttress, usually 2-4 m above the ground. The cores were properly mounted and surfaced, the annual rings were carefully cross-dated⁹ and measured, and the dating was independently confirmed. Non-climatic variance due to age trend and differential growth rates was minimized through a double-detrending

Fig. 1 Locations of baldcypress tree-ring chronologies in Arkansas. The three longest chronologies used to reconstruct June PDSI for Arkansas are: EPL, Egypt; BSW, Black Swamp; BME, Bayou Meto.

procedure, wherein negative exponential curves and stiff splines were fit in succession to the raw ring width data^{10,11}. The detrended, standardized ring width indices for all well correlated cores were averaged together by year into a robust mean value function chronology for each collection site (that is, the standard chronology). Autoregressive (AR) modelling of the tree-ring indices at each site revealed significant low-order autocorrelation in most series, believed to be due primarily to internal biological processes in baldcypress and to external ecological factors. To remove this suspected non-climatic growth persistence, a serially random residual chronology was also derived for each site¹². All ring width indices at each site were pre-whitened using second and third-order AR models selected on the basis of the Akaike final-prediction-error criterion¹², and the resulting serially-random residuals were then averaged yearly into the robust mean residual chronology for each collection site¹⁰. A small amount of variance trend remained in the standard and residual chronologies, and was stabilized by fitting a very inflexible spline to the variance¹⁰.

Direct³ and inverse¹³ correlations between growing season rainfall and the growth of certain wet-site species have been reported. Correlation and response function analyses¹⁴ of our available cypress chronologies both indicate that baldcypress radial growth is correlated directly with precipitation and inversely with temperature for several months during the current growing season, in spite of frequently flooded site conditions. Using the appropriate divisional climate data for 1931-80, these correlations range as high as +0.58 for June precipitation and -0.43 for June temperature.

The response of internal baldcypress growth regulating mechanisms to environmental conditions is not well understood, but we emphasize that baldcypress is physiologically adapted to wetland conditions and remains subject to the environmental variation inherent in its swamp habitat, as documented in part by the climatic correlations reported above. We suspect that complex factors related to and including rainfall amounts may limit the growth of baldcypress. These conditions probably include periodic drydown of the root system during drought, moderation of direct solar radiation by cloud cover, high temperatures, and lower water quality during drought. High temperatures and intense solar radiation, for example, might cause transpiration rates to exceed moisture uptake and would result in internal moisture stress even in saturated soil conditions. Field monitoring of baldcypress conditions, and improved modelling of the growth-climate relationship will be required for a better definition of the environmental response of baldcypress. Nevertheless, the observed correlations with precipitation and temperature imply that useful estimates of past summer drought can now be derived with these long baldcypress chronologies.

Statewide average PDSI has been calculated monthly from 1891 to 1982 for Arkansas¹⁵. It is based on areally-weighted divisional temperature and precipitation values from 1931 to

1982, and on adjusted equally-weighted values from all available reporting stations for 1891 to 1930. Although the number of reporting stations declines and missing values increase before 1931, records for 29 stations extend to 1891 and provide reasonably uniform spatial coverage of the state¹⁶.

Equations for calibrating the tree-ring and PDSI series to predict past drought were derived for the standard and residual chronologies using both simple and stepwise multiple regression. Calibrations were restricted to the period 1931–80 when the PDSI data are of the highest quality. Several monthly and seasonal PDSI values for the current growing season were examined as dependent variables (that is, April, May, June, July, May–June, May–July, April–July), and three tree-ring chronologies were used as independent variables.

Independent PDSI data for 1891–1930 not included in developing the calibration equations were used to verify and compare each drought reconstruction. The correlation coefficient, sign test, and the reduction of error statistic were used for verification^{14,17,18}. These tests indicate that the best results were obtained using simple linear regression between statewide June PDSI and a regional average of the three mean residual tree-ring chronologies (Fig. 2). The regression equation used for calibration is:

$$y = -5.189 + 5.102x$$

where y is the estimated June PDSI for a given year and x is the regional average of the residual chronologies for the same year. This model is significantly correlated with June PDSI ($r = 0.64$, $P < 0.0001$) during the calibration period, and explains 40% of the variance in the PDSI series after adjustment for loss of degrees of freedom (r_{adj}^2).

The verification statistics between observed and estimated June PDSI for 1891 to 1930 indicate that the reconstructed series is a stable, reliable indicator of past drought. The correlation between the observed and estimated drought series is 0.70 ($P < 0.0001$) during the 40-yr verification period, which explains some 49% of the variance in the independent climate series. The sign test indicates 29 agreements and 11 disagreements ($P < 0.01$) during the verification period. And the reduction of error (RE) for the verification period is +0.42, indicating that the model accurately reconstructs actual drought conditions. (Significance tests are not available for the RE statistic, which ranges from $-\infty$ to +1.0, but simulation experiments suggest that the approximate 95% confidence level is $RE \approx 0.0$ for $n > 10$ (ref. 18).)

Acceptable verification statistics were obtained when the standard chronologies were used in simple and stepwise multiple regression models with June PDSI, but the statistics indicate that the regional average of the residual chronologies provide the most accurate climate reconstruction (explaining some 7% more climate variance, with an RE statistic 0.14 points higher during the verification period). Removing low-order persistence from the residual chronologies has evidently enhanced the climate signal in these chronologies, implying that the persistence is largely physiological in nature and is not in phase with possible climate persistence.

The generally good agreement between the annual and multi-year departures for the observed and estimated drought series in both the calibration and verification periods is apparent in Fig. 2. Careful examination of Fig. 2 and the actual climate data suggests that the reconstruction may be even more reliable than indicated by the verification statistics. The three worst estimates during the verification period were calculated for 1895, 1928, and 1902, the three years by rank with the largest disparity between the observed and estimated June PDSI (Fig. 2). In each of these years, however, June rainfall was well above average and reversed the climate regime established in the preceding months¹⁵. Moderate June drought was reconstructed for 1895 and 1902, but heavy June rains fell in both years and broke 13 consecutive months of incipient to moderate drought in 1895, and 16 consecutive months of mild to severe drought in 1902. Normal moisture conditions were reconstructed for June of 1928, but the highest average June rainfall in 92 yr was actually

Fig. 2 Actual (dashed line) and reconstructed (solid line) statewide June PDSI for Arkansas, 1891–1980. The reconstruction was calibrated on the 1931–80 data, and verified with the pre-1931 data.

recorded for Arkansas in 1928, which produced a moderate moisture excess ($PDSI = +2.85$) and reversed five months of slightly below average rainfall¹⁵.

These examples illustrate differences in the way the Palmer Index and baldcypress trees integrate the effects of current and previous climate. Baldcypress growth is generally not well correlated with drought conditions during the preceding winter and early spring. But as the 1895, 1902, and 1928 data suggest, particularly severe or prolonged dry spells during this period can result in reduced radial growth. Improved conditions in June may be reflected by the Palmer Index, but apparently come too late on these occasions to reverse the established growing conditions for baldcypress.

If 1895, 1902, and 1928 are excluded from the verification period, the simple correlation increases to 0.79 ($P < 0.0001$) and the RE increases to +0.59. These verification tests provide convincing evidence regarding the overall accuracy and reliability of the long-term drought reconstruction.

Detrending, AR modelling, and regional averaging of chronologies from three relatively undisturbed sites has minimized but probably not entirely eliminated possible non-climatic trends from the reconstruction due to natural or artificial disturbances (such as, insect defoliation, selective logging, and land clearing). For example, the estimated series does not fully reflect the extremes in the actual data, especially after about 1950 (Fig. 2). The variance of the actual and estimated PDSI series for 1891 to 1949 is 3.55 and 2.85 respectively, but changes to 5.44 and 1.69 for 1950 to 1980. The drop in reconstructed variance after 1950 reflects reduced variance in the tree-ring chronologies. In view of this unexplained variance, the 450-yr drought reconstruction should only be considered as a conservative estimate of past moisture anomalies, and probably does not fully reflect the extremes of wetness and dryness which actually occurred.

If the drop in variance after 1950 is a real nonrandom phenomenon, it may be related to increased post-war developments in the lower Mississippi Valley. The effects of various artificial developments on baldcypress growth are likely to be complex, but greatly accelerated land clearing and land draining for agriculture in recent decades¹⁹ have changed water levels, the nutrient budget, and other ecological aspects of affected wetlands⁷ and may be among the most prominent impacts in the lower Mississippi Valley. The apparent loss of variance after 1950 needs further documentation with additional baldcypress chronologies, but suggests that the reconstruction might be improved by basing the calibration on pre-1950 data.

Reconstructed June PDSI for 1531–1980 is plotted along with a filtered version designed to pass variance with a frequency of ≥ 8 yr (Fig. 3)¹⁴. Numerous wet and dry spells comparable with twentieth century events punctuate the 450-yr reconstruction.

Fig. 3 Reconstructed statewide June PDSI for Arkansas, 1531-1980 (a) and a low-pass filtered version (b). Sample size decreases from 97 cores at 1980 to 16 at 1531, as noted above the upper plot.

Ten droughts ≥ 10 yrs in length are estimated in the filtered series for around 1555, 1570, 1595, 1670, 1765, 1835, 1850, 1875, 1900, and 1915 (Fig. 3b). Five of these droughts have occurred in the past 150 yr, including what may have been two of the three most intense and prolonged dry spells in the entire reconstruction (that is, 1875 and 1915). The prolonged droughts estimated for around 1550 and 1570 are also obvious in the filtered plot, and reflect negative PDSI values for 22 of the 29 yrs between 1549 and 1577 in the unfiltered series (Fig. 3a). This may represent the worst June drought period for Arkansas in the past 450 yr.

Another striking feature of the filtered reconstruction is the apparent increased amplitude of moisture anomalies before 1650 and after ~ 1840 (Fig. 3b). In view of the variance stabilization and good sample size throughout the reconstruction (Fig. 3), we are inclined to attribute these changes to real macroenvironmental factors.

This research demonstrates the suitability of swampgrown baldcypress for palaeoclimatic reconstruction in the southeastern United States. Some climate reconstructions based on upland species have produced better verification statistics²⁰, but very few species other than baldcypress have definite potential to provide millennia-long tree-ring chronologies in eastern North America. The additional baldcypress chronologies currently under development throughout the Atlantic and Gulf coastal plains should result in significantly longer drought histories, and should permit investigation of the spatial distribution of past moisture anomalies in the south-east.

We thank Mr and Mrs W. Wiggins, Mrs E. R. Harper, D. Harper, the Arkansas Game and Fish Commission, and the Hempstead County Hunt Club for permission to sample, and G. G. Hawks, E. R. Cook, R. L. Holmes, T. P. Harlan, G. C. Jacoby, R. Berg, and R. O. Fowler for assistance and comments. This research was supported by NSF grants ATM-8006964, ATM-8120615, and ATM-8412912.

Dioxin radical formation and polymerization on Cu(II)-smectite

Stephen A. Boyd & Max M. Mortland

Department of Crop and Soil Sciences, Michigan State University, East Lansing, Michigan 48824, USA

Decontamination of hazardous wastes containing dioxins (dibenzo-*p*-dioxin and its chlorinated analogues) remains a serious problem and new approaches for the degradation or alteration of dioxins are needed. We describe here dibenzo-*p*-dioxin radical cation formation and polymerization on a simple clay mineral (Cu(II)-smectite) in mild reaction conditions. Existence of the radical species was conclusively demonstrated using electron spin resonance (ESR), ultraviolet-visible, and infrared spectroscopy. The radical cation polymerized to form dimers and trimers as revealed by mass spectroscopy. Radical cations of 1- and 2-chlorodibenzo-*p*-dioxin were also formed on Cu(II)-smectite. The radical cations are formed by electron transfer from the dioxins to Cu(II). The formation of dioxin radicals may provide the basis for new detoxification methods in which the reactive radical species is coupled to other molecules or degraded by subsequent reactions.

One of the principle unsolved problems concerning dioxins is the development of effective and economically feasible methods to detoxify them. Large quantities of dioxin-contaminated manufacturing wastes remain buried at various sites in the US. There are also $\sim 3,000$ barrels of dioxin-contaminated wastes stored in an Environmental Protection Agency (EPA) approved shelter¹. The most widely used method for detoxification of dioxin is incineration. Other approaches including concentration, photolysis, radiolysis, ozonolysis, chloriodide degradation, wet-air oxidation, chlorinolysis, chlorolysis, catalytic dechlorination, destruction by ruthenium tetroxide and biological treatment have been described but not widely used¹⁻³.

Smectites are layer silicate clay minerals possessing a net negative charge which is compensated by exchangeable cations. Several aromatic molecules have been shown to form radical cations when adsorbed by Cu(II), Fe(III) or VO(II)-smectite⁴⁻¹⁰. This results from complete electron donation from the aromatic species to the metal cation with attendant reduction of the metal ion. Such reactions have been followed by means of infrared and ESR spectroscopy. The radical cations once formed, may then undergo polymerization as shown for benzene which forms *p*-polyphenyl polymers of various molecular weights¹⁰ and for anisole (methoxybenzene) which forms 4,4'-dimethoxybiphenyl⁸. The development of such radical cations in relatively mild reaction conditions suggests unique effects of the negatively charged silicate surface in promoting their formation. The objective of the present study was to determine if dibenzo-*p*-dioxin, 1- and 2-chlorodioxins would undergo similar radical cation formation and polymerization reactions on smectite surfaces. Earlier work has shown the existence of dioxin radical cations in homogeneous solutions of concentrated sulphuric acid with oxidizing agents such as H₂O₂ and KNO₃ (refs 11, 12) and in homogeneous solutions of trifluoromethanesulphonic acid exposed to ultraviolet light and O₂ (ref. 13).

When Cu(II)-smectite was refluxed (69 °C) in a solution of *n*-hexane in which dibenzo-*p*-dioxin (referred to as dioxin in the following discussion) had been dissolved, the normal light blue colour of the clay was replaced by a deep blue colour suggestive of the dioxin radical reported to be formed in

Fig. 1 A, *a*, Infrared spectrum of a film of Cu(II)-smectite; *b*, same film after refluxing for 2 h in hexane containing dissolved dibenzo-*p*-dioxin; *c*, after evacuation in a cell for 1 h; *d*, re-exposed to the atmosphere for 2 weeks; *e*, Ca²⁺-smectite refluxed 2 h in hexane containing dissolved dioxin. The clay films were obtained by evaporating a water suspension of the clay on sheets of polyethylene. After drying, the clay films ($\sim 1 \text{ mg cm}^{-2}$) could be peeled away from the plastic. After refluxing, the self-supporting films were placed in an evacuable infrared cell fitted with AgCl windows, and the infrared beam passed directly through the film. B, Plots of the absorbances of two bands, 1,487 cm⁻¹ (circles) and 1,286 cm⁻¹ (squares) attributed to the molecular form of dibenzo-*p*-dioxin versus a band attributed to the radical cation (1,542 cm⁻¹). The various points represent a variety of proportions of the two configurations produced by different levels of hydration of the clay films. O, Proportions of the two species as the film was dehydrated; ■, as the film was rehydrated.

homogenous solution¹¹⁻¹³. As in the work reported for other aromatic species on Cu(II)-smectite, the refluxing process probably dehydrates Cu(II) to the point where the dioxin molecule can interact with the Cu(II) through π electrons at vacant ligand positions. At this point an electron is completely transferred reducing the Cu(II) to Cu(I) and producing the radical cation of dioxin. Evidence for this reaction is from the following: infrared, ultraviolet-visible, ESR, and mass spectroscopy.

Figure 1 shows the infrared spectra of a Cu(II)-smectite film

Fig. 2 Ultraviolet-visible differential spectra of the dioxin radical on Cu(II)-smectite recorded in both absorbance (dashed line) and transmittance (solid line) modes. An aqueous suspension of Cu(II)-smectite was placed on the inside surface of both the sample and reference cells and evaporated at room temperature forming a continuous clay-film. The sample cell was then placed in a round bottom flask and refluxed in hexane which contained dioxin. Within an hour the film turned a deep blue colour indicative of the radical. The sample cell was removed from the flask, filled with hexane, and placed in the sample beam. Additional hexane was used to fill the reference cell. Spectra were recorded on a Perkin Elmer 320 spectrophotometer.

(*a*) and the same film (*b*) after refluxing in a hexane solution of dioxin, and placed in a vacuum cell. Prolonged evacuation of the cell produces maximum development of the bright blue colour (*c*), and then exposure to moist air reconverts the colour to the light blue typical of Cu(II)-smectite (*d*). Figure 1*e* shows the spectrum of dioxin on Ca²⁺-smectite. Bands unique to the molecular form of dioxin are at 1,286, 1,297, 1,377, 1,470, and 1,487 cm⁻¹. Those which form with the development of the bright colour and are, therefore, related to the radical cation are at 1,349 and 1,542 cm⁻¹. Assignment of the bands has not been made, but are probably ring stretching and deformation vibrations. Figure 1 also shows the inverse relationship of the absorbance of two molecular bands, 1,487 and 1,286 cm⁻¹, with the radical cation band at 1,542 cm⁻¹ (correlation coefficient, $r > 0.95$). These data show that as the radical cation is formed, the amount of molecular species decreases, then as moist air is admitted the band of the radical species decreases and those of the molecular species increase. Figure 1*d* shows the spectrum of the same film after standing in air and may represent mainly the dimer of dioxin which has formed by radical cation interaction with molecular forms. The molecular bands of dioxin at 1,377 and at 1,470 cm⁻¹ are missing in this material, while those at 1,286, 1,297, and 1,487 cm⁻¹ are maintained. No colour change or radical bands at 1,349 and 1,542 cm⁻¹ appeared in the Ca-system (Fig. 1*e*) even after prolonged refluxing and evacuation.

The visible spectrum of the bright blue complex is given in Fig. 2. A broad absorption band in the red region is characterized by a maximum at 685 nm and two lesser peaks at 661 and 638 nm, which are particularly well expressed in the absorbance mode. Figure 2 represents a differential spectrum since the reference beam passed through a Cu(II)-smectite film in hexane, while the sample beam passed through the Cu(II)-smectite-dioxin complex in hexane. The position of the main peak (685 nm) is not far from that of the dioxin radical (655 nm) developed in homogeneous solution¹³. This difference could easily be accounted for by the interaction of the dioxin structure with the silicate surface, which could result in minor band shifts.

The ESR spectrum of the Cu(II)-smectite-dioxin complex (Fig. 3*a*) exhibited a narrow line ($H_{pp} = 1.5 \text{ G}$) at $g = 2.0028$ conclusively demonstrating the existence of the dioxin radical cation. The Cu(II) ESR signals apparent in Fig. 3*c, d* were not observed in the dioxin spectrum demonstrating that paramagnetic Cu(II) was reduced to diamagnetic Cu(I) by electron transfer from dioxin to Cu(II). No hyperfine structure was

Fig. 3 ESR spectra of: dioxin radical cations on: *a*, Cu(II)-smectite film; *b*, standard pitch ($g = 2.0028$) Cu(II)-smectite film with H_0 oriented perpendicular (*c*) and parallel (*d*) to the clay layers. The radical cation was formed by refluxing dioxin and a mixed Cu(II)-Ca²⁺-smectite film (1:9 molar ratios of Cu:Ca) in hexane for 2 h. The film was then placed in a quartz tube which was evacuated for 2–3 h. The evacuated tube was then placed into a Varian E-4 spectrometer and the spectrum recorded. Spectra *c* and *d* were recorded in a similar fashion using mixed Cu(II)-Ca²⁺-smectite films that were not exposed to dioxin. Orientation of the clay films with respect to H_0 separated the $g_{\perp}$ and $g_{\parallel}$ components of the Cu(II) signal.

observed for the dioxin radical on Cu(II)-smectite. Proton hyperfine splitting has been observed for dioxin radical cations in homogenous solution¹³; the loss of hyperfine structure has been attributed to rapid electron exchange on the smectite surface and is consistent with ESR spectra reported previously for other aromatic molecules which form radical cations on transition metal layer silicates⁹.

Evidence for the formation of dioxin polymers on Cu(II)-smectite was obtained using mass spectrometry (Fig. 4). Molecular ions were observed for dioxin dimers (m/e 366) and

trimers (m/e 548) of the type shown in Fig. 5. The dioxin monomer (m/e 184), dimer and trimer were chromatographed separately with increasing temperature. Polymerized products of benzene, phenol, and anisole on Cu(II)-smectite have been observed previously^{8,10}.

The reaction described above for dibenzo-*p*-dioxin has also been found to proceed for 1- and 2-chlorodibenzo-*p*-dioxin as shown by brilliant blue colour development when the materials were refluxed in hexane with the mineral. Infrared absorption studies on these clay films showed development of new bands correlated with the colour formation. Thus, the radical cation

Fig. 4 Mass spectrum and mass chromatographs of a methanol extract of the Cu(II)-smectite-dioxin complex. The complex was formed by refluxing Cu(II)-smectite and dioxin (1:2 molar ratio of Cu:dioxin) in hexane for 6 h. The hexane was decanted and the solid material extracted with 15 cm³ of absolute methanol. The methanol extract was then decanted and evaporated to dryness under a stream of air. A small portion of the solid material obtained was introduced into a Hewlett-Packard 5985A mass spectrometer using a solid probe. The sample was held at 30 °C for 1.5 min then heated 30 °C min⁻¹ to a maximum temperature of 280 °C. Mass chromatographs are shown for the total ion intensity (TII) and m/e values of 184 (dioxin monomer), 366 (dioxin dimer) and 548 (dioxin trimer). The mass spectrum displayed was taken at 5.2 min.

formation is possible with chlorinated members of this group. When dibenzo-*p*-dioxin was refluxed in hexane with Fe(III)-smectite, radical cation formation was also noted, as it was observed in other work on aromatic radical cation formation in clays⁹. This was suggested by the development of a dark green colour in the clay, probably resulting from the combination of the blue of the radical cation and the colour bestowed by various valence states of iron.

Our work suggests possibilities for detoxification of dioxins (including the chlorinated congeners) through catalysis by a simple mineral material. The relatively mild reaction conditions plus the availability of a cheap and easily-prepared clay material seems attractive. Additional research may reveal the possibilities of reacting the radical cations of dioxins in the clay with other organic species to yield different kinds of reaction products which might be more desirable than polymers of the dioxin itself. The reactive radical species may also be subject to other kinds of reactions leading to the formation of less toxic products.

We thank G. M. Klecka, Dow Chemical, for providing the dioxins used in this study and T. J. Pinnavaia for assistance in obtaining ESR spectra. Partial support from the NSF under grant CHE-8306583 is gratefully acknowledged. Journal article no. 11638 of the Michigan Agricultural Experiment Station.

Hydroxymethyl hydroperoxide and bis(hydroxymethyl) peroxide from gas-phase ozonolysis of naturally occurring alkenes

S. Gäb, E. Hellpointner, W. V. Turner & F. Körte

Institut für Ökologische Chemie der Gesellschaft für Strahlen- und Umweltforschung mbH, München, D-8050 Freising-Weihenstephan, FRG

Ozonolysis is one of the main pathways for degradation of alkenes in the atmosphere, where the reaction is associated with smog formation¹ and the haze that often occurs over forests^{2,3}. In recent decades, ground-level ozone concentrations have greatly increased^{4,5}. The possibility of significant damage to plants by ozone and its products has consequently been raised in discussions of 'waldsterben', the large-scale dying of trees in northern Europe and North America⁶⁻⁹. With particular regard to the formation of peroxides, we have used ¹³C-nuclear magnetic resonance (NMR) to investigate the water-soluble products of the gas-phase ozonolysis of isoprene and several terpenes, which are emitted into the atmosphere in large quantities (10⁸–10⁹ tonnes yr⁻¹ globally) by trees^{3,10,11}. All these alkenes yield bis(hydroxymethyl)peroxide (BHMP; HOCH₂OOCH₂OH). The apparent precursor of BHMP is hydroxymethyl hydroperoxide (HMP; HOCH₂OOH), which results from addition of water to the ozonolysis intermediate. As both HMP and BHMP have various toxic effects on plant cells and enzymes¹²⁻¹⁴, we point out here an indirect way by which ozone may adversely affect forests.

Although it is a powerful tool for the determination of the structures of organic compounds, NMR has until now been neglected in favour of Fourier transform infrared spectroscopy (FTIR) and mass spectrometry (MS) in studies of gas-phase ozonolysis, because it requires larger samples and transfer of the products to solution after the reaction. Our experiments were carried out with alkene and O₃ concentrations much higher than those found naturally. In a typical experiment, alkene (2.65 mmol), H₂O (9.45 mmol; calculated to give ~50% relative humidity at atmospheric pressure) and air were introduced into an evacuated 20-l pyrex vessel to a total pressure of 100 torr, followed by ozone (6–7 mmol; ~5% in O₂) and air until atmospheric pressure was reached. An aerosol began to form immediately and after 1 h had largely settled out onto the walls of the reactor. The vessel was washed with a solution of 2 ml of D₂O in 200 ml of acetone; after removal of the acetone under vacuum, dioxane (10 mg) was added as an internal standard. The ¹³C-NMR spectra were recorded at 5–10 °C, with no pulse delay other than the 0.8 s acquisition time. The BHMP yields from some representative experiments are shown in Table 1; the reported yields have been corrected for some loss of BHMP during acetone-removal.

Isoprene and α-pinene are the main alkene components of forest air, where they occur in concentrations as high as 1–10 p.p.b., parts per 10⁹ (refs 3, 7). We have examined the ozonolysis of these compounds, 2-chloropropene, and the naturally-occurring alkenes ethene, β-pinene, 2-carene and limonene. In every reaction where O₃/alkene was ≥1, we found BHMP (δ=94.4) and formic acid (δ=168.5). In most reactions, lesser amounts of HMP (δ=95.4) and formaldehyde (δ=84.6) were also found. Although the resonances of BHMP and HMP lie close together, they were shown by admixture of the authentic

substances to be reliably separated from each other and from 1,3,5-trioxane (formaldehyde trimer) (δ=96.2) and 1,2,4-trioxolane (ethene ozonide) (δ=95.1). (Ethene ozonide is a possible product of the reaction, but would almost certainly be removed from the sample along with acetone).

Equations (1) and (2) show the pathways by which HMP and BHMP are probably formed. The alternative route to HMP in equation (3) is possible, but not necessary, as will be shown below. Reactions (3) and (2) represent the known syntheses of HMP and BHMP^{15,16}; reaction (1) has been postulated for gas-phase ozonolysis¹⁷ and is a typical reaction in aqueous solution¹⁸.

The reactants in equations (1)–(3) are all known products of ozonolysis. According to the Criegee mechanism, both CH₂OO (carbonyl oxide) and formaldehyde can be produced in the reaction of ozone with terminal alkenes [equations (4a, b)]¹⁸. In the gas phase, particularly at low pressures, most of the excited CH₂OO is lost by unimolecular reactions leading to various free-radical and molecular products including water. At pressures near atmospheric, a significant fraction of this species is collisionally stabilized, and bimolecular reactions [see, for example, reaction (1)] become more important^{19,20}.

Alkenes without the group CH₂= can also form CH₂OO and CH₂O by a route which has been suggested for both solution²¹ and gas-phase ozonolyses²². Thus, as shown in equation (5), a carbonyl oxide with a methyl substituent can stabilize itself by an internal hydrogen shift to produce a new, terminal alkene. Depending on the relative reactivities of the original and the new alkenes and the amount of ozone available, the new alkene may also be cleaved. The electronegative hydroperoxy group, however, will make the second ozonolysis highly selective for CH₂OO [equation (6)]¹⁸.

Ozonolysis in aqueous solvents produces hydrogen peroxide¹⁸, presumably by addition of water to the carbonyl oxide, followed by elimination, as in equations (7) and (8). Because of its chlorine substituent, 2-chloropropene will selectively yield CH₂OO and acetyl chloride. Here processes involving H₂O₂, as in equations (3), (7) and (8), cannot play a significant role, because addition of H₂O to CH₂OO delivers HOCH₂OOH (HMP) directly. Ozonolysis of 2-chloropropene gives a good yield of HOCH₂OOCH₂OH (BHMP), indicating that the formaldehyde needed to produce BHMP is formed under our conditions either from the reaction of CH₂OO and ozone²² or from radical reactions of the alkene and its degradation products.

Ethene and isoprene are expected to yield both CH₂O and CH₂OO, and we find that they give significant amounts of BHMP even when ozone/alkene < 1. β-Pinene also has the structural element CH₂= and, as expected, it yields a considerable amount of BHMP. Within the rather large measurement errors of ¹³C-NMR, the yield decreases only slowly as O₃/alkene drops below 1.

The case of α-pinene, which has no terminal double bond, is quite different. Here the yield of BHMP is sharply reduced as the ratio of O₃ to α-pinene decreases (Table 1, experiments 1, 2 and 3). This is consistent with the hypothesis that CH₂OO from α-pinene results from ozonolysis of the rearrangement product of the initial carbonyl oxide [equations (5) and (6)].

Table 1 Yield of BHMP from gas-phase ozonolysis

Experiment*	Alkene	Alkene (mmol)	O ₃ Alkene	BHMP (mmol)
1	α -Pinene	2.65	2.60	0.28
2		2.65	1.46	0.07
3		2.65	0.72	<0.01
4		2.65	0.85	0.06†
5	β -Pinene	2.65	2.34	0.16
6		2.65	0.84	0.10
7	Limonene	2.65	2.73	0.18
8	2-Carene	2.65	2.83	0.20
9	Isoprene	2.65	2.58	0.66
10		2.65	0.87	0.18
11	Ethene	6.67	1.06	0.64
12	2-Chloropropene	4.71	1.81	0.48

* All experiments except 12 were for 1 h at room temperature; experiment 12 was for 17 h at 5 °C.

† 3 mmol CH₂O were added to the reactor before ozonolysis.

Published data on ozonolysis of α -pinene are inconsistent about the direction of cleavage of the (presumed) primary ozonide^{3,23,24}. We find, however, that good yields of the cross ozonide shown in equation (10) can be obtained by ozonolysis of α -pinene in solution in the presence of CH₂O; this is clear evidence of cleavage as in equation (9) (to be published elsewhere). The presence of CH₂O in the α -pinene reaction can be shown, nevertheless, even with O₃/ α -pinene <1 (see Table 1, experiment 4, where formaldehyde is added), suggesting that the rate of ozonolysis of the rearranged carbonyl oxide is comparable with that of α -pinene.

Formation of BHMP in the ozonolysis of simple alkenes, for example, ethene^{25,26}, has been known for a long time. HMP was never detected among the ozonolysis products, probably because it is a liquid and less stable than BHMP. An ion at m/e 64, corresponding to the molecular ion of HMP, has been observed in the gas-phase ozonolysis of ethene and 2-methylpropene, but the investigators were unable to explain to their satisfaction how HMP could be formed in their low-pressure system¹⁷. They did, however, recognize that the addition of water would be an important loss process for carbonyl oxides in the atmosphere²⁷. The direct identification here of HMP and BHMP confirms these reports, but we emphasize that the reaction of water with CH₂OO is a possible environmental source of the peroxide HMP at elevated ground-level O₃ concentrations.

The high alkene and O₃ concentrations used here probably do not affect the sequence of reactions leading to HMP from isoprene and terpenes with terminal double bonds. In view of the huge annual emission of terpenes by plants and the availability of O₃ and water vapour, it is possible that considerable amounts of HMP are formed in the environment. The low concentrations of formaldehyde in the atmosphere make it less likely that much BHMP is formed. Similar considerations also apply to the question of whether HMP and BHMP are formed in smoggy urban atmospheres, where both ozone and alkenes (for example, ethene and propene) are known to be present¹.

There have been several investigations of the biological activities of BHMP and HMP. BHMP has been shown to be a mutagen in experiments on root meristem cells (*Vicia faba*)¹², as well as in *Drosophila*²⁸ and *Neurospora*²⁹, and it has cytostatic activity in mouse tumour cells³⁰. Several enzymes, especially those with —SH groups, are inhibited by BHMP^{13,31}; it may be significant that horseradish peroxidase is irreversibly inhibited¹⁴.

Two studies on BHMP have indicated that the effects observed resulted from a product, presumably HMP, formed by hydrolysis of BHMP in the test system^{12,13}; the possibility that these were the results of further hydrolysis of H₂O₂ could be eliminated^{29,32}. Despite the implications of these results, there appear to have been no studies of the response of whole plants or mammals to HMP and BHMP. Both of these substances are rather unstable under physiological conditions³³, and it is unknown whether they can enter intact plants. It is important that attempts be made to detect HMP in the environment and to determine whether its lifetime is long enough for it to influence vegetation.

The effect of climate on long-term changes in the crustacean zooplankton biomass of Lake Windermere, UK

D. G. George* & G. P. Harris†

* Freshwater Biological Association, The Ferry House, Ambleside, Cumbria LA22 0LP, UK

† CSIRO Division of Fisheries Research, Hobart, Tasmania 7001, Australia

Fish predation is increasingly being viewed as one of the most important factors influencing the development of zooplankton populations in lakes^{1–3}. Marine zooplankton populations, on the other hand, are thought to be influenced primarily by the climate^{4,5}. We show here that year-to-year fluctuations in the biomass of crustacean zooplankton in Lake Windermere, in the United Kingdom, are strongly correlated with variations in water temperature, but poorly correlated with the abundance of the dominant planktivorous fish. This represents the first conclusive evidence of climatologically induced variability in a freshwater planktonic ecosystem. The links between climate and fisheries have recently been summarized by Cushing⁶, who suggests that climatic events regulate fish production through the matching or mismatching of their spawning with the period of available food. Our observations, reported here, suggest that year-to-year fluctuations in the biomass of crustacean zooplankton in Windermere are similarly influenced by the matching or mismatching of seasonal events in the zooplankton with the availability of algal food.

Fig. 1 The contour diagram shows the annual and seasonal variations in the biomass of crustacean zooplankton in the north basin of Windermere between 1940 and 1980. Biomass was estimated by a simple volumetric technique²³; the values shown are dry weights m^{-2} . The left-hand histogram shows the year-to-year variations in mean June temperature, and is based on weekly measurements at a central station in the north basin. All temperature measurements were taken in the top 5 m with a combined temperature and oxygen electrode (Mackereth). The right-hand histogram shows year-to-year variations in the year-class strength of perch between 1940 and 1976¹⁰ and includes estimates of a survival index for the years 1941–1964⁹. In 1976 the perch populations in Windermere were dramatically depleted by fungal disease¹⁵.

Windermere is the largest lake in the English Lake District (54°22'N, 2°56'W); it is divided into two distinct basins by an island and a region of shallows less than 5 m deep. The north basin is 8.05 km^2 in area and 64 m deep; the more productive south basin covers 16.78 km^2 and is 42 m deep. Long-term changes in the chemistry of Lake Windermere have been summarized by Sutcliffe *et al.*⁷, and Lund⁸ has published several accounts of the indigenous phytoplankton. The numbers and biomass of perch (*Perca fluviatilis* L.) in Windermere have been recorded and analysed every year since 1941^{9,10}, and the food preferences of the young perch have also been studied periodically^{11–13}. The crustacean zooplankton samples analysed here were collected from the north basin at fortnightly intervals between 1940 and 1980. All the samples were collected at the same mid-lake station by hauling a net vertically through the water column from a depth of 40 m. The conical net used had a mouth area of 700 cm^2 , a mesh size of 240 μm and efficiently captured all crustacea larger than first- or second-stage copepods. Occasional qualitative checks showed that the crustacean zooplankton populations in the north basin have changed little in the last 40 years. More detailed studies of samples collected in the last 10 years showed that, while the absolute abundance of the various species changed from year to year, there was no major shift in species dominance. The summer zooplankton crops are dominated by the cladoceran *Daphnia hyalina* var. *galeata* Sars and the cyclopoid copepods *Cyclops strenuus abyssorum* Sars and *Cyclops leuckarti* (Claus). Appreciable num-

Fig. 2 High-resolution (—) and low-resolution (---) spectra for the 40-yr record of mean June temperature. The spectra were obtained by smoothing the raw spectra with the trapezium frequency window. The inset shows the bandwidths and smoothing window shapes for the two spectra. The main peak in the high-resolution spectrum is judged significant as its one-sided 95% confidence interval ($P < 0.05$) does not include the corresponding value in the low-resolution spectrum.

bers of the calanoid copepod *Diaptomus gracilis* Sars are present throughout the year, and two large cladoceran species *Leptodora kindti* (Focke) and *Bythotrephes longimanus* Leydig, appear for short periods in summer.

The contour diagram in Fig. 1 shows the seasonal and annual changes in crustacean zooplankton biomass that have occurred in the north basin between 1940 and 1980. It seems likely that the biomass of crustacean zooplankton has increased as a result of nutrient enrichment in recent years⁷, but the most obvious pattern is a quasi-cyclical variation with a period of about 10 years. Direct counts on a portion of this record show that the fluctuations in biomass principally reflect variations in the numbers of *D. hyalina*, the dominant herbivore. In Fig. 1 these fluctuations are compared with year-to-year fluctuations in mean June temperature and the recruitment and survival of perch. A. E. Irish (personal communication) has analysed the historical temperature records for Windermere¹⁴ and found that June is the only month in which a significant long-term autocorrelation is apparent. More detailed analyses of the Windermere temperature profiles show that these temperature variations are directly related to the timing of thermal stratification. The year-class strength records in Fig. 1 are a relative measure of the numbers of perch hatching each year and were obtained by trapping 2-yr-old fish. The assumptions inherent in these calculations have been discussed by Le Cren *et al.*⁹, who emphasize the relative nature of these estimates. A close examination of Fig. 1 suggests that the changes in crustacean zooplankton biomass are inversely related to mean June temperature, but bear very little relationship to either the year-class strength or the survival of perch. For example, the zooplankton fared poorly in 1950 and 1963 when there were few young perch in the lake, and reached quite high numbers in 1959 when perch were exceptionally abundant. The catastrophic incidence of perch disease in 1976¹⁵ also appears to have had little effect on crustacean zooplankton biomass. The very strong year-class of perch produced in 1959 may, however, have had some long-term effects, but the impact of older fish is difficult to assess as they do not feed extensively on zooplankton^{12,13}.

The overall interrelationships between crustacean zooplankton biomass, water temperature and perch recruitment are summarized by a series of multiple regressions in Table 1. Variations in the year-class strength of perch account for only 6.5% of the variation in crustacean zooplankton biomass, whereas variations in June water temperature account for almost 35% of the year-to-year variations in biomass. Such minor year-to-year variations in water temperature can have little direct effect on the survival and reproductive potential of the crustacean zooplankton; they are significant only insofar as they act as a surrogate for more

Fig. 3 Year-to-year variations in the mean summer (May to September) biomass of crustacean zooplankton in the north basin of Windermere, compared with year-to-year variations in mean June air (■) and water (●) temperature. The zooplankton biomass and water temperature data are taken from Fig. 1, and the air temperatures were obtained from a local meteorological stations. All the data were smoothed with a three-point-centred moving average with weights 0.25, 0.5 and 0.25.

fundamental weather-related factors such as wind-induced mixing.

Recently, several attempts have been made to resolve historically short-term (decades) periodicities in physical and biological data⁶. To assess the statistical significance of our temperature cycle, we have analysed our 40-year record using techniques of spectral analysis. Figure 2 shows the high-resolution and low-resolution spectra obtained from the 40-year record of mean June temperature. The peak at 9.8 yr in the high-resolution spectrum was tested by the bandpass filtering technique suggested by Hays *et al.*¹⁶ and judged significant at $P < 0.05$. The relationship between crustacean zooplankton biomass and this '10-year' temperature cycle is highlighted graphically in Fig. 3. This figure compares smoothed estimates of mean summer biomass with similar smoothed estimates of June air and water temperatures. There is a clear pattern of low zooplankton biomass in the summers following warm Junes, and high zooplankton biomass in the summers following cool Junes. The pattern is most pronounced for the temperature cycles recorded between 1940 and 1970. In the early 1970s, the weather pattern over northern Europe changed abruptly as northerly winds weakened and westerlies became dominant¹⁷. The less extreme biomass fluctuations recorded in Windermere over recent years may, in part, reflect this stabilizing influence. It is interesting that the water temperatures in Fig. 2 follow a more pronounced cycle than the air temperatures. This suggests that the onset of thermal stratification is strongly influenced by wind-induced mixing as well as by surface irradiance.

There seems little doubt that the quasi-cyclical events observed in Lake Windermere reflect a much wider pattern of climatic

Fig. 4 The quasi-cyclical element of means of sea-surface temperature recorded in Marsden square 145D (45–50°N, 10–50°W) for the period 1940–1973²⁰. The plot was derived from the original data by the application, as a filter, of the second eigenvector of the matrix of serial correlations with a maximum lag of 7 years⁵.

variation. An approximately 10-yr periodicity in sea-surface temperature has been reported for several areas of the North Atlantic by Maximov *et al.*¹⁸ and for the English Channel by Southward *et al.*¹⁹. More recently, Colebrook and Taylor²⁰ have demonstrated a pronounced temperature cycle for Marsden square 145D (southern Celtic Sea and the northern Bay of Biscay). Figure 4 shows the annual mean anomaly of sea-surface temperature taken from their paper²⁰ for the period 1940–1973. The general similarities between the pattern of change in Windermere and the western sea approaches are fairly obvious. Colebrook and Taylor believe that this cyclical pattern is determined primarily by direct heat exchange but is again mediated by the meridional component of the surface winds.

Clearly, more information is needed to fully document the links between climate and zooplankton production in Windermere. Cushing⁶ has hypothesized that fish recruitment is strongly influenced by the matching or mismatching of the period of larval production with the period of available larval food. It seems likely that a comparable match/mismatch process controls the crustacean herbivore cycle in Windermere. Our preliminary observations certainly point to the importance of physical conditions in early summer, and suggest that these conditions influence the timing of biological events in the lake. Phytoplankton succession is known to be strongly influenced by weather-related mixing episodes²¹. Experimental studies in other lake systems²² also demonstrate that the availability of algal food influences the subsequent development of the crustacean plankton.

In Windermere, stratification is followed by the sedimentation of the spring diatom crop and the growth of a variety of nanoplankton. These small, rapidly growing species are an important source of food for filter-feeding crustacea who are less able to feed on the larger, slow-growing species that occur later in summer. The long-term nanoplankton records for Windermere

Table 1 Stepwise multiple regression of mean crustacean zooplankton biomass on mean June temperature (T) and on the year-class strength of perch (p)

	d.f.	Sum of squares	Mean square	Variance ratio
Regression on p alone	1	0.023	0.023	
Further inclusion of T in regression	1	0.532	0.532	17.16 ($P < 0.001$)
Regression on both p and T	2	0.554	0.277	
Regression on T alone	1	0.452	0.452	
Further inclusion of p in regression	1	0.102	0.102	3.29 (NS)
Regression on both p and T	2	0.554	0.277	
Residual	32	1.005	0.031	
Total	34	1.559	0.046	

d.f., Degrees of freedom; NS, not significant.

have not yet been analysed in detail (J.W.G. Lund, personal communication). Preliminary studies nevertheless suggest that the critical reproductive period for the crustacean zooplankton is more likely to coincide with the period of maximum food availability in 'cool' rather than 'warm' Junes. In warm Junes the preferred food species tend to appear earlier and may be in decline by the time the *Daphnia* start to reproduce rapidly.

The samples analysed in this paper have been collected, regularly, for a period of >40 yr. The authors would like to acknowledge their debt to all FBA staff who have been involved with this sampling programme. We thank A. H. Taylor and R. T. Clarke for critical comments on the manuscript, and M. A. Hurley and G. Tunncliffe-Wilson for statistical advice.

Taxonomic affinities of the immature hominid crania from Hadar and Taung

Todd R. Olson

City University of New York Medical School,
Convent Avenue at 138th Street,
New York, New York 10031, USA

The description¹ of the AL 333-105 cranium from the East African Pliocene provides a new opportunity to re-examine the suggestion²⁻⁴ that the Taung child may be a robust rather than a gracile form of early hominid. Comparisons of these two crania with the skulls of living and fossil hominoids indicate that AL 333-105 possesses autapomorphic features associated with *Paranthropus* masticatory hypertrophy, and provide additional evidence for the existence of this lineage in the Hadar Formation. Here, I report a study of the facial morphology of the Taung specimen which, together with recent observations on its dentition⁵, provides strong evidence against the allocation of the Taung child to the *Paranthropus* clade. The identity of the specimen is recognized as being in the *Homo* lineage.

The comparison of 71 crania of *Gorilla*, 85 of *Pan troglodytes*, 67 of *Pan paniscus*, 40 of *Pongo* and 164 of *Homo sapiens* demonstrates that nasal bone outline and the relationships of the frontal, nasal and maxillary bones are highly consistent within and between these taxa. Typically, in great apes of both sexes and all age groups, nasion and glabella are closely approximated on the supraorbital torus (Fig. 1). The nasal bones are widest immediately superior to the piriform aperture and they converge superiorly. The relatively large maxillary processes of the frontal bones project inferiorly beside the nasal bones,

Fig. 1 Cladogram of extant hominoid taxa, illustrating the nasal bones and superior margin of piriform aperture in *norma frontalis*. Figures (to scale) indicate the differences between the nasal outlines and the relative positions of nasion to glabella (•).

placing the frontomaxillary sutures in a roughly transverse plane below the level of nasion.

The significance and primitive nature of this pattern in the great apes are further indicated by: (1) its presence in the orang-utan where the inter-orbital region is derived; (2) its existence in the Miocene ape *Sivapithecus*⁶; and (3) the minimal variation found between infant and adult specimens. The third observation is particularly strong evidence that great-ape nasal morphology is symplesiomorphic.

In contrast, the morphology of the nasal region in *H. sapiens* is derived in the reduction or absence of the maxillary processes of the frontal bone as seen in a frontal view, and in the location of nasion relative to glabella (Fig. 1). In *H. sapiens*, the frontonasal and frontomaxillary sutures are linear and continuous below an anteriorly projecting supraorbital torus, and nasion is removed from its primitive association with the supraorbital torus and glabella (Fig. 1).

The ontogenetic evidence for a consistent association of these features in *H. sapiens* is compelling. Fetal human crania exhibit the adult condition even in the absence of a supraorbital torus⁷. The data collected in this study from an ontogenetic series of *H. sapiens* crania⁸ agree with the developmental data from other hominoid taxa. Thus, nasal morphology is useful in determining the phylogenetic affinities of both adult and immature fossil crania.

The taxonomic relevance of nasal morphology to early hominid systematics is further increased by the existence in *Paranthropus* of a third derived pattern (Fig. 2a-d). In *Paranthropus*, the lateral margins of the nasal bones are derived from the primitive hominoid pattern in the way they diverge superiorly. However, the primitive relationships between: (1) nasion and glabella; and (2) the frontonasal and frontomaxillary sutures are retained. Nasion and glabella are closely approximated well above the points where the frontomaxillary sutures meet the nasal bones, and the nasomaxillary sutures are either parallel or divergent superiorly. The frontal profile of *Paranthropus* nasal bones is described here as a 'keystone' pattern.

Loading of the anterior dentition during occlusion has been shown⁹ to generate intense forces in the face that are transmitted through the frontal processes of the maxillae to the supraorbital torus, where they are dissipated in the cranial vault. In hominoids with a primitive triangular nasal profile (Fig. 1), the frontal processes of the maxillae act as simple pillars that transmit force directly to the beam-like supraorbital torus. The derived keystone condition in *Paranthropus* is an adaptation that more evenly distributes anterior occlusal forces through the supraorbital torus to the cranial vault.

A supported arch with its central keystone functions to distribute overlying weight evenly to laterally located pillars. The

Fig. 2 Nasal bones and superior margin of piriform aperture in specimens of *Paranthropus* from Swartkrans (a), Olduvai Gorge (b) and Koobi Fora (c, d); *Homo* (*Australopithecus*) from Sterkfontein (e), Makapansgat (f) and Koobi Fora (g); and *Homo* (*Homo*) from Swartkrans (h). *Norma frontalis* reconstructions indicate the differences in nasal profile, and the relative position of glabella (•) to nasion and to the plane between the points where the two frontomaxillary sutures meet the nasal bones.

nasal region of *Paranthropus* functions in a similar manner except that the compressive forces distributed in its arch-like structure are applied by the pillars rather than by overlying weight. In the vertical face of *Paranthropus*, compressive forces generated by anterior dental loading are transmitted through the frontal processes of the maxillae (the pillars) to the nasal keystone (the arch) where they are evenly distributed to the supraorbital torus. The adaptive significance of this arrangement is probably associated with paranthropine masticatory evolution. In *Paranthropus*, the premolars became increasingly involved with heavy chewing and were enlarged anteriorly at the expense of the canines and incisors. As a result, the forces generated during anterior dental loading would have been significantly increased¹⁰.

Hominid supraorbital morphology has been studied¹¹ with respect to the functional relationship between facial prognathism and stress resistance by the torus. Russell¹¹ concluded that a flat face optimizes the transmission of vertical bite force from the anterior dentition to the supraorbital region. Similarly, the flat *Paranthropus* face has been described^{9,12,13} as an adaptation to the anterior enlargement of the premolars and their increased role in mastication.

Although the frontal profile of the nasal bones in *Paranthropus* is derived relative to the postulated common hominid ancestor, the gracile early hominids (Fig. 2e-h) retain the primitive hominoid profile but are derived in the location of nasion relative to glabella. In Sts. 5, MLD. 6 and other members of the *Homo* lineage, the nasal bones appear truncated below the supraorbital torus, with the frontomaxillary and frontonasal sutures oriented close to a horizontal plane below the variably inflated glabellar region. The extent of this superior nasal truncation in Sts. 5 and MLD. 6 is somewhat less derived than the condition observed in later *Homo* forms. However, in both specimens, nasion is at the base of the supraorbital torus well inferior to glabella.

The nasal region has been described¹ for AL 333-105. This specimen was collected at the same Hadar Formation locality as AL 333-45, which has been shown¹⁴⁻¹⁷ to have paranthropine basicranial characteristics. The data used to reconstruct the AL 333-105 specimen (Fig. 3a) are from Kimbel *et al.*¹. However, whereas these authors conclude that the size and form of the nasal bones are 'unusual', the present results indicate the presence of a paranthropine type of pattern. Comparison of the AL 333-105 nasal morphology with the postulated primitive hominid

Fig. 3 *Norma frontalis* reconstructions of juvenile crania AL 333-105 from the Hadar Formation (a) and from Taung (b).

condition (Fig. 1) indicates a highly derived rather than a primitive morphology¹⁸.

Fortunately, the immature age of AL 333-105 does not diminish the taxonomic relevance of its nasal morphology. Continued facial growth could only further reduce the combined nasal breadth at the inferior half of the nasal bones where they are overlapped laterally by the frontal processes of the maxillary bones¹⁹. Thus, it is reasonable to conclude that the nasal profile of an adult AL 333-105 would bear an even closer resemblance to known adult specimens of *Paranthropus* (Fig. 2a-d) than does the actual condition observed in the juvenile skull.

The paranthropine nasal pattern in AL 333-105 is particularly pertinent to the suggestion²⁻⁴ that the Taung skull (Fig. 3b) may be a form of *Paranthropus*, based on its apparently young geological age. However, the affinity of the Taung specimen must be based solely on its morphological characteristics²⁰ and not on an undefined method of chronotaxonomy. The phylogenetic comparisons of the Taung child conducted in this study identifies the derived nasal pattern of the *Homo* lineage and does not support the inclusion of the Taung specimen with AL 333-105 in the *Paranthropus* clade.

Another comparative study of the Taung child⁵ has concluded that it does not possess the derived dental features that characterize *Paranthropus*. Grine's⁵ conclusions assume added significance in view of suggestions²⁻⁴ that Taung represents the terminal phase of paranthropine evolution. It could be argued that an immature individual of the earliest paranthropines might not exhibit the full suite of cranial or dental specializations seen in later forms. However, it is unlikely that the terminal individuals of this clade would exhibit few, if any, of the specializations seen in its ancestors.

I thank W. K. Kinzey, J. C. Steiner and A. F. Sweazey for their comments on this manuscript, and L. Volk and F. Pace for preparing the figures.

Phorbol ester and sperm activate mouse oocytes by inducing sustained oscillations in cell Ca^{2+}

K. S. Roy Cuthbertson & P. H. Cobbold

Department of Zoology, University of Liverpool, PO Box 147, Liverpool L69 3BX, UK

The parthenogenetic activation of mouse oocytes by several agents is accompanied by a large rise in the intracellular calcium concentration ($[\text{Ca}^{2+}]_i$)¹. The tumour-promoting phorbol ester 12-*O*-tetradecanoyl phorbol acetate (TPA) activates some cellular processes which are also activated by raised $[\text{Ca}^{2+}]_i$ (ref. 2). We therefore tested TPA on mouse oocytes and found it to be a potent parthenogenetic activating agent. Recent reports suggest that TPA mimics endogenous diacylglycerol³ and can stimulate cells by activating protein kinase C without raising $[\text{Ca}^{2+}]_i$ (refs 4, 5). We have now measured $[\text{Ca}^{2+}]_i$ with aequorin in mouse oocytes treated with TPA. Sustained oscillations in $[\text{Ca}^{2+}]_i$ appeared in those oocytes which were subsequently activated. We also measured $[\text{Ca}^{2+}]_i$ during fertilization. The response began with $[\text{Ca}^{2+}]_i$ transients as reported previously¹, but the transients continued in a regular pattern for 4 h. There was no rise in $[\text{Ca}^{2+}]_i$ of the type induced by activating agents such as ethanol. One component of the fertilization response appears to be related to the TPA-induced oscillations.

Unfertilized superovulated oocytes incubated with TPA, or the active analogue 4 β -phorbol 12,13-dibutyrate (PDB), were found to be activated when examined after 5 h, but the relatively inactive 4-*O*-methyl derivative of TPA was ineffective at the

Fig. 1 Activation of mouse oocytes by phorbol esters. Superovulated mouse oocytes (MF1; Olac, Bicester) obtained 16–18 h after the injection of human chorionic gonadotropin (HCG), were incubated in Whittingham's bicarbonate-buffered medium 16 plus the test agent, fixed after 5 h and scored under Nomarski optics for the presence of pronuclei. ○, TPA, 5 h; ●, TPA, 10 min; □, 4-*O*-methyl derivative of TPA, 5 h; ■, phorbol 12,13-dibutyrate, 5 h; ▲, dimethyl sulfoxide (DMSO) control, 5 h; Δ, medium-only control. The data are combined results from six experiments with a total of 665 oocytes. The phorbol esters (Sigma) were dissolved in DMSO (1 mg ml⁻¹). (CBA × C57BL/6)F₁ oocytes treated with 100 ng ml⁻¹ TPA for 5 h developed to morulae and blastocysts (54%, 93/171) in similar proportion to diploid controls treated¹¹ with 7% ethanol for 7 min and cytochalasin D for 5 h (53%, 67/126).

same concentrations⁶ (Fig. 1). In most (94%) of the activated oocytes the second meiotic division was suppressed. This is unusual for artificial activating agents, which usually induce a mixture of activation types⁷, and can be contrasted with fertilization, which almost invariably produces a second polar body.

Free $[\text{Ca}^{2+}]_i$ in the oocytes was measured with aequorin during treatment with a maximally activating concentration of TPA (200 ng ml⁻¹). After a variable delay of 30–80 min, small oscillations in $[\text{Ca}^{2+}]_i$ appeared in some oocytes (6/12 oocytes, observed for at least 2 h). A higher concentration of TPA (1 μg ml⁻¹) induced oscillations within 10 min (3/4 oocytes). The oscillations continued for up to 3 h (Fig. 2). All oocytes with Ca^{2+} oscillations which were examined later (five oocytes)

Fig. 2 The $[\text{Ca}^{2+}]_i$ response to 200 ng ml⁻¹ TPA in single mouse oocytes. *a*, Onset of $[\text{Ca}^{2+}]_i$ oscillations; *b*, section of oscillations showing the appearance of a 'bursting pattern' in the oscillations. Oscillations had begun in this oocyte 12 min earlier than shown, and continued for a total of 200 min. A similar bursting pattern of oscillations was seen in one other oocyte. Log *k* is log₁₀ of the fraction of aequorin consumed per s.

Methods. Mouse oocytes, taken 15–18 h after the HCG injection from (C57BL/6 × CBA)F₁ females, were injected with the photo-protein aequorin and placed in glass microslides in a chamber at 37°C under a photomultiplier as described previously^{11,12}. The oocytes were treated with 0.5 μg ml⁻¹ cytochalasin D (Sigma) for ~1 h before injection. Photon pulses were passed through a Nuclear Enterprises photon counting system or an EMI amplifier-discriminator (type C601). Photon counts were sampled every 50 ms and stored in a Sirius 1 microcomputer. Background was subtracted from the counts, which were then normalized, smoothed exponentially (time constant 5 s) and calibrated¹² to give the plots shown here. The oocytes were examined at the end of the experiments with Nomarski optics (Nikon). Both oocytes from the illustrated experiments were activated. $[\text{Ca}^{2+}]_i$ was measured until pronuclei appeared. No change in $[\text{Ca}^{2+}]_i$ other than the oscillations could have induced the activation. The medium was Whittingham's bicarbonate-buffered medium 16, modified by replacing lactate with HEPES pH 7.4, and gassed with 5% CO₂ in air. For the fertilization experiments this medium was further modified to raise pH to 7.7 and the bovine serum albumin content fivefold to 20 mg ml⁻¹.

Fig. 3 The $[Ca^{2+}]_i$ response during fertilization in single mouse oocytes. *a*, A typical series of 13 $[Ca^{2+}]_i$ transients showing their sustained periodicity. *b*, The first two transients in another oocyte, showing fast oscillations on each transient (time constant 30 s for resting level, reduced to 0.5 s for the transients). The oocyte zona pellucida was removed by digestion with α -chymotrypsin (0.03%) after the aequorin injection. Preincubated sperm from (C57BL/6 $\times$ CBA)E₁ males were added to the microslides after an initial measurement period.

were activated, with one or two female pronuclei and no second polar body; oocytes which did not develop Ca^{2+} oscillations remained unactivated (three oocytes).

The Ca^{2+} oscillations had periods of between 17 and 35 s. In each sustained series of oscillations, $[Ca^{2+}]_i$ reached $5\text{--}7 \times 10^{-7}$ M, assuming a uniform distribution of $[Ca^{2+}]_i$. However, if $[Ca^{2+}]_i$ rose in only part of the cell volume (10–30%), then locally it could have exceeded $1 \mu\text{M}$. $[Ca^{2+}]_i$ often seemed to oscillate below and above an underlying $[Ca^{2+}]_i$ concentration which could either remain constant (Fig. 2*b*), or rise or fall (data not shown). Raising $[Ca^{2+}]_i$ in TPA-treated oocytes with ethanol (7%) or benzyl alcohol (0.4%) could induce oscillations, if none were yet present, and these oscillations were superimposed on a large $[Ca^{2+}]_i$ rise of the type previously reported¹. Slower $[Ca^{2+}]_i$ rises, produced by raising external Ca^{2+} (fivefold) or occurring spontaneously, extinguished the oscillations within a few minutes. During corresponding slow falls in $[Ca^{2+}]_i$, oscillations sometimes reappeared. This suggests that calcium itself can both stimulate and inhibit the oscillations over the course of several cycles. Such a dual influence may explain the regular appearance and disappearance of the oscillations seen in Fig. 2*b*.

We measured $[Ca^{2+}]_i$ in four zona-free oocytes during fertilization. The $[Ca^{2+}]_i$ response was complex but remarkably similar in all four cells, consisting of a regular series of large Ca^{2+}

transients (reaching 2×10^{-6} M) which continued for 4 h (Fig. 3). The interval between the first two transients was about 10 min and that between the following transients was about 20 min. There were 13 transients in three oocytes and 15 in the fourth. Superimposed on the transients were faster oscillations, with a period of about 20 s on the first transients and about 10 s on the rest. The oscillations on the first transients reached 4×10^{-6} M. After the last transient there was no further change in $[Ca^{2+}]_i$ (measured for at least a further 10 h). All four oocytes were subsequently found to be fertilized, with two pronuclei and a second polar body.

The oscillations on the fertilization transients have several features in common with the TPA-induced oscillations. For example, the frequencies are similar and the oscillations appear to modulate $[Ca^{2+}]_i$ both up and down from what it would otherwise have been. Small oscillations in membrane potential (with period ~ 20 s) have been recorded during fertilization in mouse oocytes⁸; larger recurrent hyperpolarizations occur in hamster oocytes⁹ and repetitive diphasic membrane potentials have been recorded in rabbit oocytes¹⁰. These may be a consequence of $[Ca^{2+}]_i$ oscillations like those we have observed on the first fertilization transient.

The TPA- and sperm-induced $[Ca^{2+}]_i$ responses reported here are significantly different from each other, and from the alcohol-induced $[Ca^{2+}]_i$ response¹. (We have confirmed in this experimental series that ethanol and benzyl alcohol induce large stepwise exponential rises in $[Ca^{2+}]_i$ in oocytes which subsequently became activated (four oocytes).) These three types of $[Ca^{2+}]_i$ response are all capable of activating the egg. The production of a second polar body, however, seems to be more critically dependent on time-course and amplitude of the $[Ca^{2+}]_i$ response. A similar variety of receptor-mediated $[Ca^{2+}]_i$ responses may occur in other cells in which $[Ca^{2+}]_i$ controls several cellular processes, providing extensive possibilities for selective operation of the $[Ca^{2+}]_i$ messenger system.

Immunocytochemical localization in rat brain of a prolactin release-inhibiting sequence of gonadotropin-releasing hormone prohormone

Heidi S. Phillips*, Károly Nikolics†‡, Dale Branton* & Peter H. Seeburg‡

Departments of * Physiology and † Biochemistry and Biophysics, University of California at San Francisco, San Francisco, California 94143, USA

‡ Department of Molecular Biology, Genentech, Inc., 460 Point San Bruno Boulevard, South San Francisco, California 94080, USA

The structure of a precursor protein for gonadotropin-releasing hormone (GnRH) of relative molecular mass 10,000 has recently been deduced from cloned complementary DNA sequences derived from human placental messenger RNA¹. The 56-amino-acid peptide representing residues 14–69 of this prohormone exhibits potent inhibition of prolactin secretion². To investigate whether the same prohormone is synthesized in mammalian brain and describe the anatomical distribution of the prolactin-inhibiting region of this

Fig. 1 *a*, Structure of human proGnRH (1-69) in single-letter amino-acid code. Underlined sections represent the decapeptide GnRH and proGnRH-40-53 synthesized for antibody production. *b*, Radioimmunoassay with antiserum 39A showing displacement of iodinated proGnRH-40-53 by increasing concentrations of proGnRH-40-53 standard or rat hypothalamic extract.

Methods. Sera from three rabbits immunized with proGnRH-40-53 conjugated to bovine serum albumin using *N*-(maleimidobutyryloxy)-succinimide were screened by radioimmunoassay. Serum from one rabbit (39A) contained antibodies to proGnRH-40-53 and recognized proGnRH-14-69 but not GnRH or proGnRH-14-24. The assay was carried out as described for adrenocorticotrophic hormone¹⁹ with some modifications. The *p*-hydroxyphenylmaleimide derivative of proGnRH-40-53 was radioiodinated using chloramine T. Antiserum 39A was used in a 1:10,000 final dilution. Bound and free radioactivity were separated by centrifugation after addition of charcoal to the assay incubation. Hypothalami from 10 female Sprague-Dawley rats (200-250g) were homogenized in 5 volumes of phosphate buffered saline solution pH 7.4. After centrifugation (15 min, 800g) 50 μ l aliquots of the supernatant were assayed by radioimmunoassay at the indicated dilutions (undiluted, 1:10, 1:100).

Fig. 2 Dual immunofluorescence staining with anti-proGnRH-40-53 and GnRH antisera. *a, b*, A coronal section through the diagonal band of Broca demonstrating perikarya stained for both proGnRH-40-53 (*a*) and GnRH (*b*). *c, d*, Adsorption control with GnRH (10 μ g ml⁻¹). ProGnRH-40-53 antibody reacts strongly with perikarya in the diagonal band (*c*), whereas no staining is visible in the same region with GnRH antibody (*d*). *e, f*, Adsorption control with proGnRH-40-53 (10 μ g ml⁻¹). GnRH-immunoreactive cells are abundant (*f*) while no reaction is detected with proGnRH antibody (*e*). *g, h*, Coronal section through median eminence demonstrating colocalization of proGnRH-40-53 (*g*) and GnRH (*h*) within axonal terminals. Scale bar, 50 μ m for *a-f*, 40 μ m for *g* and *h*.

Methods. Sprague-Dawley rats were fixed by intracardiac perfusion with 4% paraformaldehyde at pH 7.2. Cryostat or vibratome sections of fixed tissue were stained sequentially for the localization of proGnRH-40-53 and GnRH according to the following protocol. Antiserum to proGnRH-40-53 prepared as described in Fig. 1, was preadsorbed with rat liver powder and used at a dilution of 1:2,000. Antiserum DB-1 against a Orn⁸-GnRH conjugated to bovine serum albumin was generated in rabbits, affinity purified on D-Lys⁶-GnRH-agarose, biotinylated and used at 1-2 μ g ml⁻¹. All incubation solutions contained 0.1M Tris, pH 7.2, 0.9% NaCl, 1.0% bovine serum albumin, 0.1% Triton and 0.1% Merthiolate. Tissue sections were first incubated with anti-proGnRH-40-53 for 6 h at 20 °C or 24 h at 4 °C followed by rhodamine labelled goat anti-rabbit IgG (10 μ g ml⁻¹) for 4 h at 20 °C. To saturate free binding sites on the anti-rabbit IgG, sections were incubated in 20% normal rabbit serum for 1 h. All subsequent incubations were at room temperature and contained 20% normal rabbit serum. Biotinylated anti-GnRH was applied as the second primary antibody (12 h) and was recognized by fluorescein-avidin DCS (Vector, 2.5 μ g ml⁻¹, 1 h). The fluorescent signal associated with the anti-GnRH antibody was then amplified by incubation with biotinylated goat anti-avidin (Vector, 5 μ g ml⁻¹, 1 h), followed by a second layer of fluorescein-avidin (5 μ g ml⁻¹, 1 h). Sections were mounted in glycerol and examined with a Zeiss epifluorescence microscope with fluorescein and rhodamine filter sets.

molecule, we have generated antiserum to a synthetic peptide containing residues 40-53 of the human placental precursor. We report here that a substance recognized by this antibody is present in GnRH-containing neurones of the rat brain and appears to coexist with GnRH in secretory granules of nerve terminals in the median eminence. These results indicate homology between hypothalamic and placental prohormones for GnRH and are consistent with the suggestion elsewhere in this issue² that a prolactin-inhibiting factor (PIF) is generated from this prohormone and cosecreted with GnRH by nerve terminals in the median eminence.

Antiserum was generated in rabbits to a synthetic peptide comprising residues 40-53 of the human placental precursor to GnRH (Fig. 1a). This peptide (referred to as proGnRH-40-53) represents the mid-portion of the 56-amino-acid peptide which exhibits potent inhibition of prolactin secretion². Radioimmunoassay using this serum revealed the presence in rat brain of an antigen characterized by parallel displacement with synthetic proGnRH-40-53 (Fig. 1b).

A double-label immunofluorescence technique demonstrated the coexistence of GnRH and proGnRH-40-53 in neurones of

Fig. 3 Distribution of proGnRH-40-53 immunoreactivity in rat brain. Schematic diagram of sagittal section through rat brain depicts the location of micrographs *a-d*. *a*, Coronal section demonstrating numerous immunoreactive perikarya in the diagonal band of Broca and a dense terminal field in the OVLT (arrowheads). *b*, Sagittal section displaying immunoreactive perikarya in the parolfactory region. *c*, Sagittal section depicting immunoreactive fibres along the surface of the third ventricle in the region of the subfornical organ. *d*, Coronal section through median eminence with numerous terminals immunostained for proGnRH-40-53. Scale bars, 50 μ m.

Methods. Brains from male and female Sprague-Dawley rats were fixed for immunocytochemistry by intracardiac perfusion of the animals with 4% paraformaldehyde. GnRH and proGnRH-40-53 immunoreactivities were detected in alternate vibratome sections by a modification of the avidin-biotin peroxidase complex (ABC) method²⁰. Antibody to proGnRH-40-53 (39A) was prepared as described above. Antisera to GnRH were provided by B. Kerdelhue (4,150-11) and S. Vigh (16). Primary antibody incubations (4,150-11, 1:4,000-1:8,000; 16, 1:5,000-1:10,000; 39A, 1:1,000-1:2,000) were conducted for 12-24 h at 4°C. Antibodies and ABC reagents (Vector) were diluted in Tris buffered saline at pH 7.2 containing 1% normal goat serum, 0.1% Triton X-100 and 0.1% gelatin. In some instances, primary antibodies (diluted 1:10 in 0.1 M Tris) were preadsorbed with rat liver powder (Cappel Labs) or rate cerebellum powder for up to 24 h at 4°C to reduce non-specific staining. Controls for specificity of staining with antibody to proGnRH-40-53 were conducted by preincubation of each ml of diluted serum with 10 μ g synthetic proGnRH-40-53. The only nonspecific interaction of proGnRH-40-53 antiserum noted was with a population of multipolar cells in the olfactory tubercle.

the septal-preoptic area (Fig. 2*a, b*). Perfect correspondence was observed between cells immunoreactive for the two antigens. Specificity of staining was demonstrated by preadsorption of the primary antibodies with synthetic GnRH or proGnRH-40-53 (Fig. 2*c-f*).

Previous studies on the biosynthesis of GnRH have revealed high relative molecular mass immunoreactive forms of the hormone in mammalian brain³⁻⁵. Our findings indicate that GnRH-containing neurones of rat brain produce a peptide homologous in sequence to the M_r 10,000 (10K) human placental precursor for GnRH. This apparent homology complements studies suggesting the presence of a single gene for GnRH^{1,6}. Thus, GnRH synthesis in human brain is likely to occur via a precursor identical to the 10K sequence present in human placenta.

To characterize the anatomical distribution of the prolactin release inhibiting sequence of GnRH prohormone, alternate sections through the entire rat brain were stained with antibodies to GnRH or proGnRH-40-53 by immunoperoxidase labelling (Fig. 3). Similar to previous reports for GnRH-immunoreactive perikarya in the rat⁷⁻¹⁰, GnRH and proGnRH-40-53-like antigens were localized to smooth-contoured bipolar neurones and irregularly outlined monopolar cells residing in the septo-preoptic region. The distribution of cells immunoreactive for proGnRH-40-53 was identical to that observed for GnRH and included the medial septal nucleus, the diagonal band of Broca (Fig. 3*a*), the nucleus triangularis septum, the medial preoptic area, the anterior hypothalamus and the parolfactory region near the midline which extends from the anterior commissure to the olfactory bulb (Fig. 3*b*). The largest concentration of

immunoreactive perikarya was located in the diagonal band of Broca near the organum vasculosum of the lamina terminalis (OVLT).

The pattern of immunoreactivity observed in rat brain with antiserum to proGnRH-40-53 was not restricted to neuronal perikarya, but also appeared in axons and terminals. Many axons stained for proGnRH-40-53 were visible throughout septal, preoptic and hypothalamic regions. Bundles of immunoreactive axons were observed along the ependymal lining of the third and lateral ventricles (Fig. 3*c*). Dense networks of terminals appeared in the OVLT (Fig. 3*a*) and median eminence (Fig. 3*d*). Extrahypothalamic projections to the olfactory bulb, amygdala, habenula and mesencephalic central grey were noted. In every region examined, the appearance of projections immunoreactive for proGnRH-40-53 was identical to that observed for GnRH. Double-label immunofluorescence experiments on tissue from septo-preoptic and hypothalamic regions (Fig. 2*g, h*) revealed perfect correspondence between axons immunoreactive for GnRH and proGnRH-40-53. The presence of proGnRH-40-53-like antigen in axons and nerve terminals as well as perikarya is consistent with earlier immunocytological evidence that cleavage of GnRH from its prohormone occurs in axonal varicosities and terminals¹¹ as described for other neuropeptide systems¹²⁻¹⁴.

At the ultrastructural level, large dense-cored vesicles immunoreactive for proGnRH-40-53 were observed in terminal and preterminal varicosities of the median eminence (Fig. 4). Within terminals immunoreactive for proGnRH-40-53, virtually every vesicle exhibited deposition of reaction product. These

Fig. 4 A proGnRH-40-53 immunopositive axonal varicosity in the median eminence. Reaction product is associated with large vesicles (arrows). Scale bar, 1 μ m.

Methods. Tissue fixation and immunocytochemical procedure was identical to that described for light microscopy with the following exceptions: 0.5% glutaraldehyde was included in the fixative and triton concentrations of 0.025% rather than 0.1% were used throughout the immunocytochemical procedure. After development of reaction product, the tissues were prepared and examined by electron microscopy as described previously²¹.

results are similar to earlier observations on GnRH-immunoreactive vesicles in nerve terminals of rat median eminence¹⁵⁻¹⁷. Given the complete overlap between terminals immunoreactive for GnRH and proGnRH-40-53 in the median eminence (Fig. 2g, h), coexistence of these peptide sequences within individual vesicles is indicated.

Extracts of hypothalamic tissue have long been known to contain prolactin release inhibiting activity¹⁸. As the 56-amino-acid carboxy-terminal GnRH prohormone fragment exhibits potent inhibition of prolactin release², our data are consistent with the idea that a prolactin release-inhibiting peptide is processed from the GnRH prohormone and secreted from terminals in the median eminence into the pituitary portal circulation. The coexistence of this peptide with GnRH in extra-hypothalamic axonal projections suggests additional roles for this substance in the regulation of neuronal activity and/or behavioural processes.

We thank B. Kerdelhué and S. Vigh for their gift of GnRH antisera, J. Burnier for the synthesis of proGnRH-40-53 and its derivatives, L. Y. Jan, Y. N. Jan and J. Ramachandran for valuable discussions and Jeanne Arch for typing the manuscript. This work was supported by NRSA NS 07282 to H.S.P., by Genentech Inc., by Howard Hughes Medical Institute, and grants NS 15757 and 16033 (NIH) to L. Y. Jan and Y. N. Jan, CA 16417 (NIH) and INT 8217148 (NSF) to J. Ramachandran.

Antigen-dependent increase in cytosolic free calcium in specific human T-lymphocyte clones

E. Nisbet-Brown, R. K. Cheung, J. W. W. Lee & E. W. Gelfand

Division of Immunology/Rheumatology, Research Institute, Hospital for Sick Children, 555 University Avenue, Toronto, Canada M5G 1X8

Calcium has been implicated as an intracellular messenger in the cellular response to various external stimuli. Exposure of lymphocytes to various mitogens and lectins results in rapid transmembrane calcium fluxes¹⁻³ and increased cytoplasmic calcium concentrations ($[Ca^{2+}]_i$)⁴⁻⁷. It is not clear, however, whether the mechanisms by which these non-physiological stimuli activate cells are related to those involved in antigen-specific activation. We have now used antigen-specific T-cell clones^{8,9} to study changes in $[Ca^{2+}]_i$ associated with specific activation and show here that these cells respond specifically in the presence of antigen and antigen-presenting cells (APC) with increased $[Ca^{2+}]_i$ and that this increased $[Ca^{2+}]_i$ shows the same genetic restrictions as are seen in the proliferation assay^{8,10,11}. The kinetics of the $[Ca^{2+}]_i$ response to antigen indicate that antigen undergoes a time-dependent processing step as a prerequisite for recognition by T cells, as has been shown for T-cell proliferative responses¹²⁻¹⁴, but that the $[Ca^{2+}]_i$ response to processed antigen is extremely rapid. The close correlation between changes in $[Ca^{2+}]_i$ and cell activation resulting in proliferation suggests that Ca^{2+} may act as an intracellular messenger in antigen-specific responses.

Until recently, it has been impossible to study $[Ca^{2+}]_i$ directly in cells responding to antigen. The fraction of cells that respond specifically to antigen in an unselected population is small compared with that activated by mitogens, and even substantial changes in $[Ca^{2+}]_i$ in this subpopulation would not be detectable using current techniques which measure the average $[Ca^{2+}]_i$ in a population. To overcome this problem we have derived tetanus toxoid (TT)-specific human T-cell clones from an immunized HLA-DR2, 7 donor by modifications of previously described techniques^{8,10,15}. Peripheral blood mononuclear cells (PBM) were restimulated *in vitro* with TT for 4 days, and responding cells were cloned at one cell per well in the presence of autologous feeder cells and TT. Clones were expanded with autologous feeder cells plus TT during the initial 4 weeks and were subsequently propagated with interleukin-2 (IL-2)-enriched T-cell growth factor preparations. This procedure was adopted to obviate outgrowth of nonspecific cells induced by exogenous IL-2 during the cloning procedure. Clones were reselected every 14-21 days with irradiated feeders and TT in the absence of exogenous IL-2. Several stable clones were isolated and screened for major histocompatibility complex (MHC) restricted antigen recognition using a 3-day *in vitro* proliferation assay in the presence of irradiated APC and antigen¹⁰.

We identified several clones recognizing TT in the context of conventional HLA-DR antigens (1C1, 2C3, 3B11), and also several anomalous clones, one of which had apparent allo-reactivity for histocompatibility antigens, as well as specific reactivity for TT + 'self'-MHC. We confirmed the dual specificity of this latter clone (1C1, see below). Detailed functional characterization of these clones will be presented elsewhere (E.N.-B. *et al.*, in preparation).

Intracellular free calcium levels were measured using the

Fig. 1 Cytoplasmic free calcium concentrations ($[Ca^{2+}]_i$) in cloned human T cells after specific activation by antigen. Cells of clone 1C3 (HLA-DR7 restricted) were loaded with Quin-2, and $[Ca^{2+}]_i$ measured at intervals after the following additions: ●, none; ■, autologous HLA-DR2, 7 APC; ▲, autologous APC + TT (0.5 LF ml $^{-1}$). Cloned cells show a progressive rise in $[Ca^{2+}]_i$ only in the presence of antigen and APC.

Methods. T-cell clones: PBM were isolated from a TT-immune HLA-DR2,7 donor by centrifugation on Ficoll-Hypaque, and restimulated *in vitro* for 4 days. Cultures were collected and cells from the largest 20% size fraction were cloned at one cell per well with the Autoclone attachment on a Coulter EPICS-V flow cytometer in the presence of autologous irradiated (4,000 R) PBM and 0.5 LF ml $^{-1}$ TT. Wells showing growth were fed weekly for 3 weeks with fresh irradiated APC and antigen, and subsequently fed twice weekly with a mixture of 10% of a culture supernatant from the MLA-144 cell line²² and 10% of a PHA-induced PBM culture supernatant²³. Every 2–3 weeks, clones were reselected with fresh autologous APC and antigen. Cloned cells were screened for antigen specificity with a 3-day *in vitro* proliferation assay against irradiated PBM from members of a panel of HLA-DR typed donors and 0.5 LF ml $^{-1}$ TT⁸. Proliferative and $[Ca^{2+}]_i$ responses were maximized if cloned cells were deprived of IL-2 in culture for 24–48 h before assay. A similar finding has been reported in mice²⁴. The proliferative responses of cloned T cells were compared with and without Quin-2/AM loading (5 μ M). Comparable stimulation indices (25–50) were observed despite the presence or absence of Quin-2 from the responding cells. Cytoplasmic free calcium determinations: Cloned cells were loaded with Quin-2 by incubation of a suspension of 1×10^7 cells ml $^{-1}$ in RPMI-1640 medium + 10% fetal calf serum (FCS) with 5 μ M Quin-2/AM for 60 min at 37 °C, then washed and resuspended at 1×10^7 cells ml $^{-1}$ (ref. 14). Antigen-presenting cells (4,000 R irradiated PBM) were added at 1×10^7 cells ml $^{-1}$ and TT at a final concentration of 0.5 LF ml $^{-1}$ where indicated. For measurement of fluorescence, aliquots of this suspension were diluted 1:20 in HEPES-buffered phosphate-buffered saline containing 1 mM Ca^{2+} (ref. 14). Quin-2 fluorescence emission was measured at 492 nm with excitation at 395 nm. After each measurement, 100% saturation of the Quin-2/ Ca^{2+} complex was determined in the presence of 1 μ M ionomycin. Cell auto-fluorescence was measured after addition of 0.5 mM Mn^{2+} , which quenches fluorescence of the Quin-2/ Ca^{2+} complex. $[Ca^{2+}]_i$ was calculated from % Ca^{2+} /Quin-2 saturation⁶. Results could not be accounted for by simple leakage of Quin-2 from damaged cells. Quin-2 fluorescence emission in the supernatant fluid after removal of cells by centrifugation was minimal and comparable in all groups, whether stimulated by APC + antigen or unstimulated.

trapped fluorescent indicator Quin-2, which binds Ca^{2+} with 1:1 stoichiometry and shows markedly enhanced fluorescence on binding calcium¹⁶. Cells were loaded with Quin-2 by preincubation with its membrane-permeant acetoxymethyl ester (Quin-2/AM), which undergoes intracellular hydrolysis to the impermeant form¹⁷. The concentration of Quin-2/AM used (5 μ M) in preincubation was not high enough to cause concentration-dependent direct metabolic and mitogenic effects^{4,7}. $[Ca^{2+}]_i$ was calculated as described previously^{4,6}. In preliminary experiments to determine the magnitude and time course of the $[Ca^{2+}]_i$ response, Quin-2-loaded cells of clone 1C3 (HLA-DR2, 7; HLA-DR7-restricted) were mixed with autologous irradiated PBM

Fig. 2 *a*, Kinetics of the $[Ca^{2+}]_i$ response of clone 2C3 (HLA-DR2 restricted) to APC-associated antigen. Assay was carried out as described in Fig. 1 legend. $[Ca^{2+}]_i$ was determined 10 and 180 min after the following additions at $t=0$: ●, none; ■, HLA-DR2, 7 (autologous) APC; ▲, HLA-DR2, 7 APC + 0.5 LF ml $^{-1}$ TT; ○, HLA-DR2, 7 APC pulsed for 3 h with 0.5 LF ml $^{-1}$ TT, and washed extensively. *b*, Kinetics of the $[Ca^{2+}]_i$ response of cells from 1C1, a T-cell clone with dual specificity for HLA-DR7 + TT and for a non-HLA-DR alloantigen present on an HLA-DR7, 8 cell. $[Ca^{2+}]_i$ was determined at $t=0$, 10 min and 180 min after the following additions: ●, none; ■, HLA-DR2, 7 (autologous) APC; ▲, HLA-DR2, 7 APC + 0.5 LF ml $^{-1}$ TT; ▼, HLA-DR7, 8 stimulator cells.

(as a source of antigen-presenting cells) in the presence or absence of TT. Changes in fluorescence intensity in the cloned cells were followed over time. Possible changes in $[Ca^{2+}]_i$ in the antigen-presenting cells do not interfere with these measurements, as the APC are not labelled with Quin-2. Cloned cells in the presence of autologous feeder cells and TT showed a rise in $[Ca^{2+}]_i$ over a period of 2–3 h, from a basal level of 115 nM to a maximum of 280 nM (Fig. 1). This slow response contrasts with those to phytohaemagglutinin (PHA) or concanavalin A (Con A), in which increased $[Ca^{2+}]_i$ occurs within 2–3 min^{5–7}, but is comparable with that observed following addition of *Staphylococcus* protein A (ref. 14). No increase in $[Ca^{2+}]_i$ was observed in cells of this clone in the presence of TT or of feeders alone. Several other clones were screened using this technique (Table 1). The antigen specificity and MHC restriction of these clones, as reflected in the $[Ca^{2+}]_i$ response, were in all instances concordant with that from 3-day *in vitro* proliferation studies, measured by ^3H -thymidine incorporation. Autologous feeder cells incubated overnight with TT and then washed free of excess antigen induced overall increases in $[Ca^{2+}]_i$, comparable to those seen with autologous feeders plus soluble TT, although the time course of the response was different (see below) (Table 1, clones 1C3 and 3B11).

The 2–3-h latency of the $[Ca^{2+}]_i$ response to soluble antigens and certain mitogens such as *Staphylococcus* protein A may reflect the need for time-dependent antigen 'processing' by accessory cells for efficient antigen presentation and recognition. The latent period should therefore be markedly reduced if the responding T cells are exposed to processed, APC-associated antigen^{12,13}. We tested this prediction for clone 2C3 (Fig. 2*a*). Autologous feeders pulsed with TT for 3 h at 37 °C and then washed extensively induced a rapid (<10 min) increase in $[Ca^{2+}]_i$ from 141 to 235 nM in the responding T cells. Cloned cells in the presence of unpulsed feeders and soluble TT showed no increase in $[Ca^{2+}]_i$ between 0 and 10 min, although $[Ca^{2+}]_i$ did rise slowly to 250 nM over 2 h in these conditions, confirming our earlier findings. Similar results have been reported for protein A, which requires monocyte-macrophage processing to induce $[Ca^{2+}]_i$ and proliferative responses¹⁴. Antigen processing or presentation is rate limiting for the $[Ca^{2+}]_i$ response, and sequential measurement of $[Ca^{2+}]_i$ thus provides a rapid and sensitive means of following events in antigen processing.

Finally, we identified several T-cell clones expressing apparent dual specificity for TT + self-MHC, and for allogeneic MHC. Clones of this type have been described previously in

Table 1 Cytoplasmic calcium concentrations in T-cell clones specifically activated by antigen

Clone	$[Ca^{2+}]_i$ (nM),				
	$t = 0$	$t = 2$ h	$t = 2$ h	$t = 2$ h	$t = 2$ h
	+0	+DR2, 7*	+DR2, 7 + TT	+DR7, 8*	+DR7, 8 + TT
1C1	135	138 (<1)	210 (5)†	ND	ND
1C3	115	135 (<1)	280 (44)†	ND	ND
			244‡		
2C3	135	146 (1)	253 (47)†	152 (1)	153 (1)†
3B11	123	147 (1)	285 (11)†	142 (1)	150 (1)†
			198‡		146‡
3D6§	134	142 (<1)	161 (<1)†	142 (<1)	275 (7.4)†

Cytoplasmic calcium concentrations were determined as described in Fig. 1 legend. $[Ca^{2+}]_i$ was determined at $t = 0$ and $t = 2$ h. Values in parentheses indicate stimulation index obtained in a 3-day *in vitro* proliferation assay. ND, not done.

* APC (4,000 R irradiated PBM) of the indicated HLA-DR type added at $t = 0$.

† APC (4,000 R irradiated PBM) of the indicated HLA-DR type + 0.5 flocculation units (LF) per ml soluble TT added at $t = 0$.

‡ APC of the indicated HLA-DR type, incubated for 3 h at 37 °C with 0.5 LF ml⁻¹ TT and washed free of excess antigen, added at $t = 0$.

§ Clone 3D6 recognizes TT in the context of a private HLA-DR specificity on HLA-DR 7, 8 APC (E.N.-B. *et al.*, in preparation).

the mouse¹⁸, but not in humans. One such clone, 1C1, proliferated in response to soluble TT and autologous HLA-DR2, 7 PBM, and also to non-HLA-DR antigens on a semi-allogeneic HLA-DR7, 8 stimulator cell. This was also seen in the $[Ca^{2+}]_i$ response: autologous PBM plus soluble TT stimulated a $[Ca^{2+}]_i$ response of 2 h latency, while semi-allogeneic stimulator cells alone induced a rapid increase in $[Ca^{2+}]_i$ (Fig. 2b; compare with Fig. 2a). Although these studies do not elucidate the mechanism of alloantigen recognition by this clone, the time course of activation implies that alloantigen is seen directly¹⁹, rather than in association with self-MHC after processing²⁰.

These results suggest that the changes in $[Ca^{2+}]_i$ seen following antigen-specific activation of lymphocytes are similar to those in cells activated by nonspecific mitogens. There is, however, a lag phase in the $[Ca^{2+}]_i$ response to antigen that is compatible with antigen processing. It is unclear if changes in $[Ca^{2+}]_i$ following exposure to mitogens are involved in the control of lymphocyte proliferation and differentiation or occur secondarily. Mitogenic lectins such as PHA and Con A can bring about increases in $[Ca^{2+}]_i$ in conditions in which a proliferative response is not obtained, as can the non-mitogenic lectin wheat germ agglutinin (WGA)⁶. Conversely, proliferative responses can be obtained in the virtual absence of extracellular Ca^{2+} , in cells exposed to PHA and co-mitogens such as phorbol esters²¹. The fact that levels of $[Ca^{2+}]_i$ increase rapidly in response to appropriate antigenic stimulation, and correlate directly with cell activation leading to proliferation *in vitro*, supports a role for increased $[Ca^{2+}]_i$ as an intracellular messenger in activation.

This technique provides a new and sensitive method to study early events in lymphocyte activation by antigens, and also to address the cellular mechanisms involved in antigen processing and presentation⁷.

This work was supported by the MRC of Canada and the National Cancer Institute of Canada. E.N.-B. is the recipient of a MRC Centennial Fellowship. We thank Dr J. A. Falk and the Histocompatibility Laboratory, Toronto Western Hospital, for HLA typing, and Drs G. B. Mills and S. Grinstein for advice and comments.

Stimulated neutrophils from patients with autosomal recessive chronic granulomatous disease fail to phosphorylate a M_r 44,000 protein

Anthony W. Segal, Paul G. Heyworth, Shamshad Cockcroft* & Margaret M. Barrowman*

Departments of Haematology and *Experimental Pathology, Faculty of Clinical Sciences, University College London, London WC1E 6HX, UK

Phagocytosing neutrophils, monocytes, macrophages and eosinophils produce a burst of non-mitochondrial respiration that is important for the killing and digestion of microbes. Much of the information about the oxidase system involved comes from studies on patients with chronic granulomatous disease (CGD), a syndrome in which an undue predisposition to infection results from complete absence of this burst of stimulated respiratory activity¹. The basis of the oxidase activity is an electron transport chain, the only established component of which is a very unusual *b*-type cytochrome (*b*₂₄₅) (ref. 2). The molecular defect in the X-linked subgroup of CGD is the absence of this cytochrome *b*₂₄₅, which, however, appears to be normal in those subjects with the autosomal recessive mode of inheritance³. In an attempt to identify an abnormality of activation, or an absence or malfunction of a proximal component of the electron transport chain in this latter group, we examined protein phosphorylation in neutrophils after activation of the oxidase with phorbol myristate acetate. All four of the patients studied demonstrated a selective lack of the enhanced phosphorylation of a protein of relative molecular mass (M_r) 44,000 (44K) that was observed in normal subjects and in two CGD patients with an X-linked inheritance. This molecule, therefore, could be an important functional component of the oxidase.

Neutrophils exposed to soluble and particulate activators of the oxidase, including phorbol myristate acetate (PMA), which is known to activate protein kinase C directly⁴, have been shown to rapidly phosphorylate a number of proteins⁵⁻⁷. We studied the time course and dose response of phosphorylation of human neutrophil proteins in intact cells stimulated with PMA. Figure 1 shows that many proteins become phosphorylated in ostensibly resting cells, and that at least 10 of these, including some with apparent M_r s similar to those described previously⁵⁻⁷, undergo enhanced phosphorylation on stimulation. The most marked incorporation occurred in bands with M_r s of 40, 44, 47, 50 and 64K and a broad band between 70 and 90K. This activated phosphorylation occurred rapidly, with obvious changes after 5 s, and continued to increase for at least 6 min.

The rate of increase in ³²P-incorporation was not uniform

Fig. 1 Protein phosphorylation in normal neutrophils at varying times after stimulation with PMA. *a-d* Represent the distances migrated by M_r markers: *a*, 77K; *b*, 66.7K; *c*, 45K; *d*, 25.7K, and the arrow indicates the position of the 44K phosphorylated protein. **Methods.** Cells (4×10^7) were purified from peripheral blood¹¹, washed in Tyrode's solution¹⁹ containing bovine serum albumin (0.025% w/v), then incubated for 1 h at 37 °C in 1 ml of the same solution containing 1 mCi ^{32} P (Amersham International, PBS.11); 10 μ g of PMA in 10 μ l dimethyl sulphoxide (DMSO) were added and 100- μ l aliquots taken at timed intervals (0-320 s) into 1 ml of cold 10% trichloroacetic acid. After 1 h the precipitates were pelleted at 12,000 r.p.m. at 4 °C for 3 min, then washed twice in Na phosphate (50 mM, pH 7.4)-buffered saline. The pelleted proteins were solubilized in SDS sample buffer and separated by SDS-polyacrylamide gel electrophoresis on 10% polyacrylamide slab gels using the Laemmli system of buffers²⁰. The dried gels were autoradiographed against Fuji-Rx film for 3 days (top). The zero time track (lower trace at bottom of figure) and the 320-s track (upper trace) were scanned with a Joyce-Loebl Chromo-scan 3.

throughout all the bands, being very rapid in some—for example, that at ~40K—and slowly progressive in others, particularly that with a M_r of ~44K. Phosphorylation was clearly dependent on concentration of PMA. Stimulation was detected at 1 ng ml⁻¹, reached a plateau at 100 ng ml⁻¹ and remained constant thereafter to a concentration of 100 μ g ml⁻¹. We chose standardized conditions for the stimulation of 10^7 cells, that is, 10 μ g PMA ml⁻¹ for 1 min and 10 min for most of the subsequent studies.

Eight normal subjects were examined and a consistent pattern of stimulated phosphorylation observed. We then examined the pattern of phosphorylation in four subjects with the very rare autosomal recessive form of CGD. Two of these were siblings from Uppsala in Sweden while the other two were English women (one was patient no. 25 in ref. 3). Cells from all four patients showed a specific absence of the normal enhancement of the phosphorylation of a protein with an apparent M_r of 44.0 ± 0.99 K (mean $\pm$ s.d. of 21 electrophoresis tracks from eight subjects: Figs 2, 3). The protein bands in this region of the gel, which were stained with Coomassie blue, appeared normal. Faint bands of phosphorylation were sometimes observed in this part of the gel in unstimulated cells from both these patients and controls; however, the normal stimulated increase in phosphorylation was never observed in the patients (Fig. 3). Apart from the abnormality in this band, the pattern of protein phos-

Fig. 2 Protein phosphorylation in control (*a, b*) and autosomal recessive CGD (*c, d*) neutrophils. Cells were prepared as described in Fig. 1 legend and treated for 10 min with 10 μ l DMSO (*a, c*) or an equal volume of DMSO containing 10 μ g PMA (*b, d*). Subsequent procedures were as described for Fig. 1. The protein of specific interest (arrow) demonstrates enhanced phosphorylation in the normal subject but not in the patient. The distances migrated by the M_r markers are indicated.

Fig. 3 Densitometry scans of autoradiographs in the region of the 44K protein. In each case the lower scan was performed on the track from unstimulated cells, and the upper scan on the track from stimulated cells. The scans were then superimposed to facilitate comparison of the same region of the gel. The 44K phosphoprotein is indicated by the arrows. Enhanced phosphorylation of this band is not observed in cells from the patients with CGD inherited in an autosomal recessive manner (*b*), whereas it is seen in cells from their corresponding control subjects (*a*) and in two patients with an X-linked pattern of inheritance (*c*).

phorylation was normal in cells from these patients.

To ensure that the absence of enhanced phosphorylation of the 44K protein band in these patients was specific for this subgroup of the syndrome and not a consequence of the failure of the oxidase system as a whole, two patients with classical X-linked CGD were studied. An entirely normal pattern of phosphorylation was observed after activation of the cells from both patients (Fig. 4): an English man (patient 4 in ref. 3) and a Greek Cypriot boy, whose cells lack cytochrome *b*₂₄₅ (ref. 3).

To quantitate these changes, the autoradiographs were scanned with a Joyce Loebl Chromoscan 3 gel scanner (slit width of 0.1 mm at an absorbance of 1.0). None of the patients with the autosomal recessive variant of the syndrome demonstrated any increase in absorbance in the region of the 44K band (limit of detection ~1 mm), whereas their paired control subjects

Fig. 4 Protein phosphorylation in control (a, b) and X-linked CGD (c, d) neutrophils. Cells were prepared and treated as described in Fig. 1 legend. a, c, Cells treated with DMSO alone; b, d, cells treated with DMSO and PMA. The distances migrated by the M_r markers are indicated, and the arrow shows the position of the band of phosphorylation of specific interest.

showed a rise in peak height of 15.3 ± 2.8 mm (mean $\pm$ s.d.) and in the X-linked patients these values were 22.9 and 12.1 mm (Fig. 3). In comparison, another band with an apparent M_r of 40K that generally becomes heavily phosphorylated (Fig. 1) showed a normal enhancement in the patients. The increase in this peak of absorption was 75.5 ± 32.1 mm in the healthy subjects, 81.6 ± 30.1 mm in the autosomal patients and 94 and 66 mm in the X-linked patients.

The subcellular distribution of this 44K phosphorylated protein was determined in stimulated and unstimulated neutrophils fractionated on discontinuous sucrose gradients⁸. The enhancement of phosphorylation after stimulation appeared to be roughly equally distributed between the membrane and granule fractions, with little activity in the cytosol. This distribution corresponds with that of cytochrome *b*, as would be expected if the two molecules interact. Phagocytosis of latex particles opsonized with human IgG also resulted in the enhanced phosphorylation of this 44K band, which was detected in association with purified phagocytic vacuoles⁹ (data not shown).

The only other study of protein phosphorylation in CGD that we have found is that by Andrews and Babior⁶ in which they investigated three patients, two males and one female, using basically similar techniques to those used in the present study. However, although the female patient, at least, probably had the autosomal recessive variant of the disease, they failed to observe any abnormalities of phosphorylation in these patients. This discrepancy could be a reflection of the heterogeneity¹⁰ of the syndrome or a minor technical difference.

After we identified the electron transport chain and its very unusual cytochrome *b*₂₄₅, we then examined its composition and integrity in CGD, the condition resulting from an absence of the oxidative burst. In a large study the cytochrome was shown to be missing from the cells of all patients with the X-linked condition, but present and ostensibly normal in those patients with the autosomal recessive mode of inheritance^{3,11}. The cytochrome, however, does not receive electrons on stimulation of the cells with an activator of the oxidase, a situation compatible with the absence of a proximal electron donor or a defect of activation^{3,11}.

Other components of the chain have not been identified, but an FAD-containing flavoprotein has been implicated since the earliest studies on the 'enzyme' system¹²⁻¹⁷. However, the flavoprotein component of the oxidase has not been clearly defined or shown to be abnormal in CGD, largely because these proteins are more difficult to study than cytochrome *b* because of their lower extinction coefficient, broad spectrum of light absorbance, the ease with which the flavin dissociates from the apoprotein and the high abundance of these proteins in neutrophils.

As shown here, there is clearly a specific defect of phosphorylation in the cells of patients with autosomal recessive CGD, an abnormality that provides the first real lead to the molecular

lesion in these subjects. In view of the different genetic pools of the patients this abnormality is unlikely to result from the expression of a gene linkage that is unrelated to the oxidase. Normal phosphorylation in the X-linked condition indicates that it is unrelated to the absence of oxidase activity. It could be that this protein is a proximal electron-transporting molecule in the oxidase chain or some other essential component, and that it fails to become activated because of defective phosphorylation. This is more likely to be due to an abnormality of the protein, possibly an amino-acid transposition, with substitution of serine or threonine, the normal targets of phosphorylation¹⁸, than a defect of the phosphorylating system, as other proteins show enhanced phosphorylation in their stimulated neutrophils. The band of phosphorylation observed in the same region of the gels in resting cells from these patients could indicate a different protein or phosphorylation of sites on the same protein that are not associated with activation by PMA.

We thank the MRC and Wellcome Trust for financial support and Drs C. Ellis, P. Down and P. Venge for allowing us to study patients under their care and for blood samples.

Human γ -chain genes are rearranged in leukaemic T cells and map to the short arm of chromosome 7

Three gene families that rearrange during the somatic development of T cells have been identified in the murine genome. Two of these gene families (α and β) encode subunits of the antigen-specific T-cell receptor and are also present in the human genome¹⁻⁵. The third gene family, designated here as the γ -chain gene family, is rearranged in murine cytolytic T cells but not in most helper T cells⁶⁻⁸. Here we present evidence that the human genome also contains γ -chain genes that undergo somatic rearrangement in leukaemia-derived T cells. Murine γ -chain genes appear to be encoded in gene segments that are analogous to the immunoglobulin gene variable, constant and joining segments⁴. There are two closely related constant-region gene segments in the human genome. One of the constant-region genes is deleted in all three T-cell leukaemias that we have studied. The two constant-region γ -chain genes reside on the short arm of chromosome 7

Fig. 1 Restriction map and nucleotide sequence of the human $C_{\gamma}1$ constant-region gene segment. **a**, The $C_{\gamma}1$ constant-region segment lies on a 5.0-kb *EcoRI* restriction fragment. The location of the constant-region coding block (cross-hatched region) was determined by hybridization with a mouse γ cDNA probe. The locations of the *EcoRI* (R), *HindIII* (H), *PstI* (P) and *BamHI* (B) restriction enzyme sites are indicated. The nucleotide sequence of the coding block was determined by dideoxynucleotide sequencing using M13 cloned fragments and sequencing in the directions shown by the arrows. **b**, Nucleotide sequence of the human $C_{\gamma}1$ constant-region fragment (hum) compared with the mouse γ constant-region segment (mou). The predicted amino-acid sequence (hum aa) and the differences between the human and the mouse proteins (asterisks) are indicated above the nucleotide sequence of the human gene.

Methods. **a**, A cDNA library was constructed from MD26 (a murine cytolytic T cell) poly(A)⁺ mRNA^{18,19} as described previously²⁰. The library was screened with a 14-base oligonucleotide (ACTGTGCAGTCTGG, provided by Ellen K. Doran) as described previously²⁵. The nucleotide sequence of the isolated cDNA was identical to the cDNA isolated by Saito *et al.* (ref. 6 and data not shown). Human B-cell lymphoma (U266) DNA was digested with *EcoRI*, and the 5.0- and 7.2-kb fragments that hybridized with the murine cDNA probe were cloned into pBR322 (ref. 20 and see text also).

(7p15); this region is involved in chromosomal rearrangements identified in T cells from individuals with the immunodeficiency syndrome ataxia telangiectasia⁹⁻¹² and observed only rarely in routine cytogenetic analyses of normal individuals¹³⁻¹⁶. This region is also a secondary site of β -chain gene hybridization¹⁷.

Segments encoding human γ -chain constant-region genes were cloned using the murine complementary DNA probe (see legend to Fig. 1a; C.M. and J.G.S., unpublished results). Southern blots of human DNA using a γ -chain probe derived from the murine T cell MD26 (refs 18, 19) revealed two weakly hybridizing bands (data not shown). Two *EcoRI* fragments of 5.0 and 7.2 kilobases (kb) were partially purified from digests of human peripheral blood DNA by fractionation on a preparative agarose gel²⁰. Subgenomic libraries were constructed from these partially purified DNA fragments by cloning into the bacterial plasmid pBR322. Three independent plasmids encoding the 5.0-kb fragment were isolated from ~200,000 plasmids containing the size-fractionated genomic DNA. The subgenomic libraries were screened with the murine γ -chain cDNA probe. Figure 1a shows a partial restriction map of the 5.0-kb fragment and the location of the γ -chain exon within it.

The nucleotide sequence of the constant-region portion of the γ gene encoded by the 5.0-kb *EcoRI* fragment was determined (Fig. 1). The 5.0-kb fragment contains only a single exon of the human γ gene and this segment is highly homologous to the murine γ gene constant-region segment (Fig. 1b). This segment is bounded by sequences that are characteristic of RNA splicing signals and thus could be a functional coding block²¹. The human and murine constant-region gene segments are identical at 274 of 330 base pairs (bp) (83% homology). The human gene segment would encode a protein that is 75% homologous to the putative murine polypeptide.

To determine the number of γ constant-region genes that exist in the human genome and to determine whether these genes are rearranged in the human leukaemia-derived T cells, we have analysed Southern blots of human B- and T-cell DNA. Southern blots of peripheral blood lymphocyte DNA obtained from two patients with mature T-cell leukaemia and from one patient with an immature T-cell leukaemia, as well as B-cell lines from the same individuals, were probed with a 300-bp *PstI/Bam* fragment (Fig. 1a) that encodes part of the constant-region segment and its 5' flanking sequence. Only two strongly hybridizing bands were identified in *EcoRI*, *HindIII*, *PstI*, *SstI*, *BamHI* and *PvuII* digests of human B-cell DNA (Fig. 2, lanes

B1, B2 and B3, and our unpublished results). Because both *EcoRI* bands were identified in the Southern blots of DNA from 20 different individuals (C.M. and J.G.S., unpublished data), we believe that these two fragments encode non-allelic constant-region genes. We suggest that there are only two constant-region segments that are more than 80% homologous to the murine γ -chain constant-region segments, although other, more distantly related constant-region genes may exist.

If the γ genes of human T cells undergo somatic rearrangement, we would expect these constant region-containing gene fragments to be altered in human T-cell DNA. The DNAs from two mature T-cell leukaemias (Fig. 2, lanes T1 and T2) and from one immature T-cell leukaemic line (Fig. 2, lane T3) were analysed by Southern blotting. The 5.0-kb *EcoRI* and 2.8-kb *HindIII* fragments are deleted in the leukaemic T cells. The small amounts of these fragments seen in lanes T1, T2 and T3 of Fig. 2 are contaminating peripheral blood T cells. These differences do not result from polymorphic differences between the different

Fig. 2 Southern blots of human B- and T-cell DNAs probed with a human C_{γ} probe (*PstI/BamHI* in Fig. 1a). DNAs from two mature adult T-cell leukaemic lines (Falc (T1) and Sylv (T2)), one immature T-cell leukaemic 8402T (T3), and B-cell lines from the same individuals, referred to as B1 (CF2K), B2 (HLS) and B3 (RPMI 8392), were digested with *EcoRI* (a) and *HindIII* (b) fractionated on agarose gels, transferred to nitrocellulose filters and hybridized using methods described previously²⁰. The sizes of the hybridizing fragments were determined by co-migration with bacteriophage λ *HindIII* fragments. kb, kilobases.

Fig. 3 The γ -chain constant-region locus is assigned to the short arm of chromosome 7 at band 7p15 by chromosomal *in situ* hybridization. *a*, Photograph of metaphase chromosome spread from a normal human male, stained with quinacrine mustard dihydrochloride and visualized by incident ultraviolet light. *b*, Photograph of the same metaphase spread as in *a*, visualized by a combination of incident ultraviolet and transmitted visible light. A grain can be seen on the short arm of one chromosome 7 in the region of 7p15. *c*, Distribution of silver grains for 233 metaphase spreads derived from PHA-stimulated peripheral blood lymphocytes following hybridization with a $C_{\gamma}1$ -derived probe (the *PstI/BamHI* fragment indicated in Fig. 1). The histogram corresponds to the standard chromosome idiogram²⁹. Significant hybridization is seen on the short arm of chromosome 7 in band p15; 10% of all metaphases contained a grain on 7p15.

Methods. Metaphase chromosomes were prepared from PHA-stimulated peripheral blood lymphocyte cultures established from two normal males according to standard cytogenetic protocols³⁰. A subclone containing the *PstI/BamHI* fragment (Fig. 1*a*) was labelled with tritium by nick-translation as described previously³¹. *In situ* hybridization, autoradiography, and chromosome banding and analysis were performed as reported elsewhere³¹.

individuals from which the T-cell leukaemic lines were isolated, as the B-cell lines were isolated from the same individuals. Thus, these T-cell leukaemias appear to have undergone a specific deletion of one constant-region segment. Two models can be proposed to account for the deletions of these constant-region gene segments: one possibility is that the gene rearrangements are related to translocations occurring during the somatic development of the T cells; a more likely possibility is that these deletions occur during the somatic formation of an active γ -chain gene. Either these cells have undergone this recombination on both chromosomes, or one of the chromosomes encoding the γ -chain gene locus has been lost from these T cells, as has been reported in T cells derived from some patients with aplastic anaemia²².

We needed to localize the γ -chain gene locus on the chromosome to determine whether chromosomal rearrangements occur at or near it. Because the β -chain genes appear to hybridize with the germline locus of the β -chain genes and with a secondary site¹⁷ in human peripheral blood lymphocytes, we used two independent approaches to map the γ -chain gene locus. First, we used *in situ* hybridization of a γ -chain probe to metaphase chromosomes derived from phytohaemagglutinin (PHA)-stimulated human peripheral blood cells (Fig. 3). Analysis of 233 metaphase spreads obtained from two normal individuals revealed that ~2.6% of the silver grains were located on or adjacent to chromosome 7 at band 7p15. The 300-bp *PstI/BamHI* hybridization probe was chosen for these experiments because several other fragments derived from the cloned 5.0-kb *EcoRI* fragment contained reiterated sequences. Secondary peaks of grain accumulation were noted at 1q32 (1.3%), 11p15 (1.1%), 11q12 (1.1%) and 14q24 (1.2%). The significance of these secondary peaks of hybridization remains to be elucidated.

The second approach to mapping the γ -chain locus involved the use of human/mouse somatic cell hybrids. The constant-region probe showed hybridization to *SstI*-digested genomic DNA derived from a hybrid cell line containing only human chromosome 7 and a hybrid cell line containing several human chromosomes and a portion of human chromosome 7 including the short arm (refs 23, 24 and T.B.S., J.G.S. and C.M., data not shown). Thus, two independently derived hybrid cells containing human chromosome 7 also contain the γ -chain locus.

The assignment of the γ -chain gene locus to 7p15 is of note for two reasons. Interestingly, earlier studies demonstrated that human T-cell β -chain gene probes hybridize to this chromosomal band in addition to the primary assignment at 7q32 (refs 17, 25). We now question whether the secondary peak of hybridization is related to the presence of the γ -chain locus at 7p15. However, we note that the secondary peak is not a result of direct cross-hybridization between the β - and γ -chain genes as the cloned segments do not cross-hybridize (A. Duby, C.M. and J.G.S., unpublished). Alternative explanations for the weak hybridization of the β -chain gene probes to the short arm of chromosome 7 include the presence of another gene family more closely related to β -chain genes than to γ -chain genes or a form of somatic recombination occurring in T cells that moves β -chain genes to the γ -chain locus.

Furthermore, previous cytogenetic analyses have revealed two instances of chromosomal rearrangements involving the short arm of chromosome 7. In particular, metaphase preparations from peripheral blood lymphocyte cultures from individuals with the autosomal recessive immunodeficiency disorder ataxia telangiectasia have shown characteristic rearrangements involving 7p14-15, 7q32-35, 14q11-12 and 14q32 (refs 9-12). Similar sites of rearrangement have been noted occasionally in karyotypes of normal individuals also. Each of these loci include genes that rearrange during somatic development of T cells. We have demonstrated here that the 7p14-15 region of rearrangement contains the γ -chain locus; earlier studies mapped the β -chain locus to 7q32 (ref. 17), and the α -chain genes have been mapped to 14q11 (refs 26-28). We now suggest that the α -, β - and γ -chain loci are good sites for chromosomal translocations because they are involved in site-specific DNA rearrangements. Future studies should determine whether these translocations merely reflect accidents that occur during somatic development of T cells, or whether they play an important part in the development of the immune response or in the oncogenic transformation of T cells.

We thank Drs A. Duby and K. Bloch for technical advice, T. Vasicsek for size-fractionated DNA, L. A. Juergens for cytogenetic assistance and Dr O. Weinberger for MD26 poly(A)⁺ RNA. We also thank Ellen R. Doren for providing the synthetic oligonucleotide. This work was supported in part by grants to Dr P. Leder from E. I. duPont de Nemours and Company, Inc.

In mammals, several well-defined metabolic changes occur during infection, many of which are attributable to products of the reticuloendothelial system¹⁻³. Among these changes, a hypertriglyceridaemic state is frequently evident⁴⁻⁹, resulting from defective triglyceride clearance, caused by systemic suppression of the enzyme lipoprotein lipase (LPL)⁹. We have found previously that macrophages secrete the hormone cachectin, which specifically suppresses LPL activity in cultured adipocytes (3T3-L1 cells)¹⁰⁻¹⁷. When originally purified from RAW 264.7 (mouse macrophage) cells, cachectin was shown to have a *pI* of 4.7, a subunit size of relative molecular mass (*M_r*) 17,000 and to form non-covalent multimers¹⁷. A receptor for cachectin was identified on non-tumorigenic cultured cells and on normal mouse liver membranes¹⁷. A new high-yield purification technique has enabled us to determine further details of the structure of mouse cachectin. We now report that a high degree of homology exists between the N-terminal sequence of mouse cachectin and the N-terminal sequence recently determined for human tumour necrosis factor (TNF)^{18,19}. Purified cachectin also possesses potent TNF activity *in vitro*. These findings suggest that the 'cachectin' and 'TNF' activities of murine macrophage conditioned medium are attributable to a single protein, which modulates the metabolic activities of normal as well as neoplastic cells through interaction with specific high-affinity receptors.

Cachectin bioactivity (LPL suppression) was assayed using 3T3-L1 cells^{20,21} described previously¹⁷. TNF activity was measured using the standard cytotoxicity assay with actinomycin D-treated L-929 cells²².

A 50-fold concentrate of crude cachectin, derived from lipopolysaccharide-stimulated RAW 264.7 cells, was prepared using a PM-10 membrane in a stirred cell (Amicon) as described previously¹⁷. Before removal of the sample from the ultrafiltration cell, octyl glucoside (Sigma) was added to a concentration of 1% (w/v). (Addition of a non-ionic detergent was essential to achieve high recovery in subsequent steps.)

The sample was passed through a 0.22 µm filter, and applied to a Mono Q (high-performance anion exchange) column

Fig. 1 Mono Q (FPLC anion exchange) chromatography. Crude concentrated RAW 264.7 medium, containing octyl glucoside as a dispersing agent, was applied to the column. Cachectin was eluted using a 0.3 M to 0.5 M Tris-Cl gradient, run at a flow rate 0.33 ml min⁻¹, over 34 min. Absorbance at 280 nm is indicated by the solid tracing. The dashed line indicates the molarity of Tris-Cl buffer used in elution. The cross-hatched area indicates the distribution of cachectin bioactivity, expressed in linear units (each point represents the result of a single bioassay). Inset photograph: a silver-stained²⁷ SDS polyacrylamide gradient gel (10% to 15% acrylamide) showing separation of crude material and successive column fractions (1 µl per lane). Relative molecular mass markers are presented in the far left lanes. The arrow indicates the band corresponding to cachectin (*M_r* 17,000 (17K)). Approximately 60% of the total protein elutes in the non-retained fraction (not shown). The peak of cachectin bioactivity elutes at a concentration of 0.38 M Tris-Cl. The three fractions with highest activity were pooled for further purification.

(FPLC; Pharmacia); ~60% of the total protein passed directly through the column. Cachectin eluted as a sharp peak at a concentration of 0.38 M Tris-Cl, pH 7.8 (Fig. 1); ~80% of the hormone was recovered in three fractions.

These fractions were pooled, lyophilized and redissolved in 0.4 ml distilled water. The sample was then subjected to high-performance gel-filtration chromatography (Superose 12; Pharmacia) (Fig. 2). Cachectin consistently eluted at a position corresponding to an *M_r* of 87,000 consistent with a pentameric

Table 1 Amino-acid composition of cachectin and TNF

	Cachectin	TNF		Cachectin	TNF
Asn/Asp	16	7/5	Leu	17	18
Thr	6	6	Tyr	8	7
Ser	12	13	Phe	6	4
Gln/Glu	20	10/10	His	3	3
Gly	13	11	Lys	10	6
Val	13	13	Arg	5	5
Ala	13	13	Pro	ND	10
Met	2	0	Cys	2	2
Ile	5	8	Trp	ND	2

ND, not determined.

* From the composition established by Pennica *et al.* for human TNF¹⁸.

structure. The molecule readily dissociates in the presence of SDS or 6 M urea, but remains intact in the presence of non-ionic detergents. It is unclear whether a pentameric conformation is essential for bioactivity.

The trailing edge of the cachectin peak was estimated to be >95% pure, and contained approximately 10^7 U cachectin bioactivity per mg protein, as did homogeneous solutions produced by means of the older purification method¹⁷. TNF activity was assayed in this preparation; $\sim 1.2 \times 10^7$ U per mg protein was measured in purified samples, compared with 3.7×10^4 U per mg in a sample of crude material. The specific activity of purified human TNF has been reported to be 2.9×10^7 U per mg protein²³.

The remaining cachectin-rich Superose 12 fractions, to be used in determinations of the amino-acid composition and sequence, were further purified by reverse-phase chromatography, using a C8 column (Supelco) as described previously²⁴. Cachectin eluted at a concentration of 30–40% acetonitrile. Forty pmol of the highly purified protein was hydrolysed with 6 M HCl and used for compositional analysis; 200 pmol was used in sequencing. (A Waters HPLC system, and a microsequencing apparatus (Applied Biosystems model 470 A) were used.)

Comparison of the amino-acid composition of mouse cachectin with that of human TNF (determined by DNA sequencing)¹⁸ reveals strong similarities (Table 1). Both proteins are acidic and hydrophobic, containing identical numbers of threonine, valine, alanine, histidine, arginine and cysteine residues.

N-terminal sequence analysis of mouse cachectin discloses a striking homology with the N-terminal sequence of human TNF (Fig. 3). All but 5 of the first 19 residues are in agreement. These data, considered together with the cytolytic effect of purified cachectin on L-929 cells, suggest that a single protein species is responsible for the cachectin and TNF activity of murine macrophage conditioned medium. Furthermore, this protein seems to be highly conserved.

We have demonstrated previously that cachectin is bound by a specific receptor, present in $\sim 10,000$ copies per cell on cultured 3T3-L1 adipocytes and C2 myotubules¹⁷. The K_d of the hormone-receptor interaction was determined to be 3×10^9 M⁻¹ by Scatchard analysis. Normal mouse liver membranes also bind cachectin in a competitive fashion. A decline in enzymatic activity is observed immediately following addition of the hormone¹¹, and apparently results from the specific inhibition of LPL biosynthesis. Net protein synthesis and cell viability are unimpaired (refs 11, 25 and S. R. Price and P. H. Pekala, manuscript in preparation).

Fig. 3 The N-terminal amino-acid sequence of mouse cachectin, top line, aligned with the corresponding sequence of human TNF¹⁸, bottom line. Equivocal residues are indicated by '?'. Matching residues are underlined.

Fig. 2 Superose 12 (FPLC gel filtration) chromatography. Pooled fractions from Mono Q fractionation were lyophilized, redissolved in distilled water, and applied to the column. Chromatography was carried out in 0.1 M ammonium acetate at a flow rate of 0.3 ml min⁻¹. A sample volume of 0.2 ml was used in each separation. The solid tracing represents absorbance at 280 nm. The cross-hatched bar indicates the presence of cachectin, as assessed by measurement of bioactivity. Arrows indicate the elution position of M_r markers applied to the Superose column. Inset photograph: SDS polyacrylamide gradient gel (10% to 15% acrylamide) showing the electrophoretic profile of successive fractions (1 μ l aliquot per lane) derived from Superose 12 gel filtration. L and P, M_r standards; Q, pooled Mono Q fractions (starting material for the Superose 12 separation).

Tumour necrosis factor has previously been studied as a cytolytic agent, capable of killing transformed cells with a high degree of selectivity^{22,26}, after a lag time of 8–16 h. The molecular basis of this selective cytotoxicity has remained elusive. Moreover, the function of the protein *in vivo* has not been established.

However, it is now clear that mouse TNF can bind to receptors present on several normal (non-transformed) murine tissues, and of evoking a specific biochemical response (LPL suppression) in adipocytes¹⁷. As the receptor for TNF is not restricted to adipocytes, we suggest that TNF, when elaborated *in vivo*, elicits specific metabolic responses in various normal host tissues. Moreover, specific suppression of protein biosynthesis might lead to the cytolytic effect observed when certain tumour cells are exposed to the hormone.
